Ionization / Excitation Diagnostics: The BPT diagram

- Ionization / Excitation Mechanisms in galaxies
 - The optical line emission from star-forming galaxies is usually dominated by emission lines from H II regions.
 - Some galaxies have strong continuum and line emission from an active galactic nucleus (AGN). The line emission is thought to come from gas that is heated and ionized by X-rays from the AGN.
 - ▶ **Seyfert galaxies:** The AGN spectrum normally includes strong emission lines from high-ionization species like C IV and Ne V, which are presumed to be ionized by X-rays from the AGN. Seyfert (1943) discovered that some galaxies had extremely luminous, point-like nuclei, with emission line widths in some cases exceeding 4000 km/s.
 - ▶ **LINERs** (Low Ionization Nuclear Emission Region): In other cases, the nucleus has strong emission lines but primarily from low-ionization species. LINERs were first identified by Timothy Heckman (1980). [There are debates on the sources of ionization and line emission; AGN or star-forming regions, shock or photoionization]
- **BPT diagram:**
 - Baldwin, Phillips & Terlevich (1981) found that one could distinguish star-forming galaxies from galaxies with spectra dominated by AGNs by plotting the ratio of $[\text{OIII}]5008/\text{H}\beta$ vs. $[\text{NII}]6585/\text{H}\alpha$.
 - These lines are among the strongest optical emission lines from H II regions.
 - The line ratios employ pairs of lines with similar wavelengths so that the line ratios are nearly unaffected by dust extinction.

-
- Recall the structure of H and He ionization zone:
 - In H II regions where He is neutral (no photons with $E > 24.6 \text{ eV}$), N and O will be essentially 100% singly ionized throughout the H ionization zone.
 - On the other hand, for O stars that are hot enough ($24.6 < E < 54.6 \text{ eV}$) to have an appreciable zone of He ionization, the N and O in this zone can be doubly ionized.
 - Because **N and O have similar second ionization potentials** (29.6 and 35.1 eV for N and O, respectively), to a good approximation, HII regions will have:

$$\text{N}^+/\text{N} \approx \text{O}^+/\text{O} \quad \text{and} \quad \text{N}^{+2}/\text{N} \approx \text{O}^{2+}/\text{O}$$

- Essentially all of the gas-phase O and N in the H II region will be either singly or doubly ionized. Hydrogen will fully ionized in the H II region:

$$n(\text{N}) = n(\text{N}^+) + n(\text{N}^{+2}), \quad n(\text{O}) = n(\text{O}^+) + n(\text{O}^{+2}), \quad \text{and} \quad n(\text{H}) = n(\text{H}^+)$$

- Let's define the fraction of doubly-ionized ion.

$$\xi_{\text{N}} \equiv \frac{n(\text{N}^{+2})}{n(\text{N}^+) + n(\text{N}^{+2})} = \frac{n(\text{N}^{+2})}{n(\text{N})}$$

$$\xi_{\text{O}} \equiv \frac{n(\text{O}^{+2})}{n(\text{O}^+) + n(\text{O}^{+2})} = \frac{n(\text{O}^{+2})}{n(\text{O})}$$

Then, the fractions are approximately equal:

$$\xi_{\text{N}} \approx \xi_{\text{O}} \implies \xi$$

-
- We assume the N abundance to be solar, and the O abundance to be 80% solar (20% is presumed to be in silicate grains).
 - In terms of the fraction,

$$\frac{n(\text{N}^+)}{n(\text{H}^+)} = (1 - \xi) \frac{n(\text{N})}{n(\text{H})}$$

$$\frac{n(\text{O}^{2+})}{n(\text{H}^+)} = \xi \frac{n(\text{O})}{n(\text{H})}$$

- Then, the line ratios can be written:

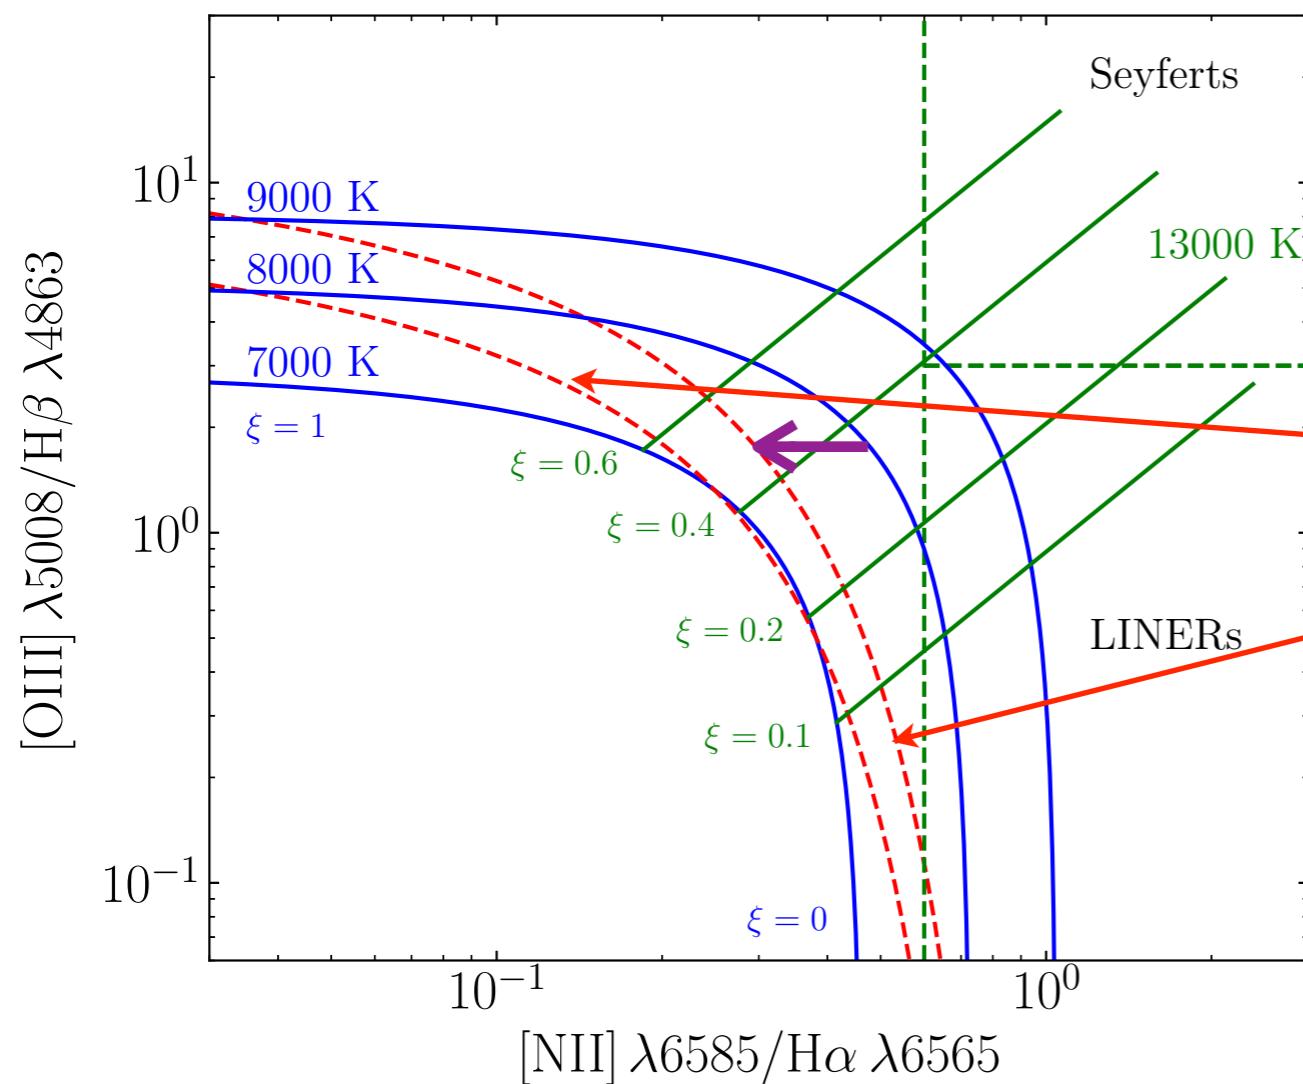

$$\frac{[\text{O III}] 5008}{\text{H}\beta} = 218.7 \xi T_4^{0.494 + 0.089 \ln T_4} e^{-2.917/T_4} \left(\frac{n_{\text{O}}/n_{\text{H}}}{0.8 \times 5.37 \times 10^{-4}} \right)$$

$$\frac{[\text{N II}] 6585}{\text{H}\alpha} = 12.44 (1 - \xi) T_4^{0.495 + 0.040 \ln T_4} e^{-2.185/T_4} \left(\frac{n_{\text{N}}/n_{\text{H}}}{7.41 \times 10^{-5}} \right)$$

- Then, for an assumed temperature T, we can produce a theoretical curve of [OIII]5008/H β versus [NII]6585/H α by varying the fraction ξ of the N and O that is doubly ionized.

The theoretical curve of [OIII]5008/H β versus [NII]6585/H α that is obtained by varying the fraction is shown below:

Blue lines show the tracks of the equations calculated, by varying ξ from 0 to 1, for $T = 7000, 8000$, and 9000 K.

Empirical curves that discriminate the star-forming galaxies from AGNs.

$$\log_{10} ([\text{OIII}]/\text{H}\beta) = 1.10 - \frac{0.60}{0.01 - \log_{10} ([\text{NII}]/\text{H}\beta)}$$

$$\log_{10} ([\text{OIII}]/\text{H}\beta) = 1.3 - \frac{0.61}{0.05 - \log_{10} ([\text{NII}]/\text{H}\beta)}$$

Kauffmann et al. (2003, MNRAS, 346, 1055)

To derive the equation, we assumed that $\xi_N = \xi_O = \xi$. The discrepancy between the simple model with the observations would be due to the assumption. We need to note that $E(\text{N}^+ \rightarrow \text{N}^{2+}) < E(\text{O}^+ \rightarrow \text{O}^{2+})$, which implies that $\xi_N \gtrsim \xi_O$.

The arrow ← indicates the direction that is expected from $\xi_N > \xi_O$.

- Line ratios for 122,514 galaxies in SDSS DR7 with S/N > 5.

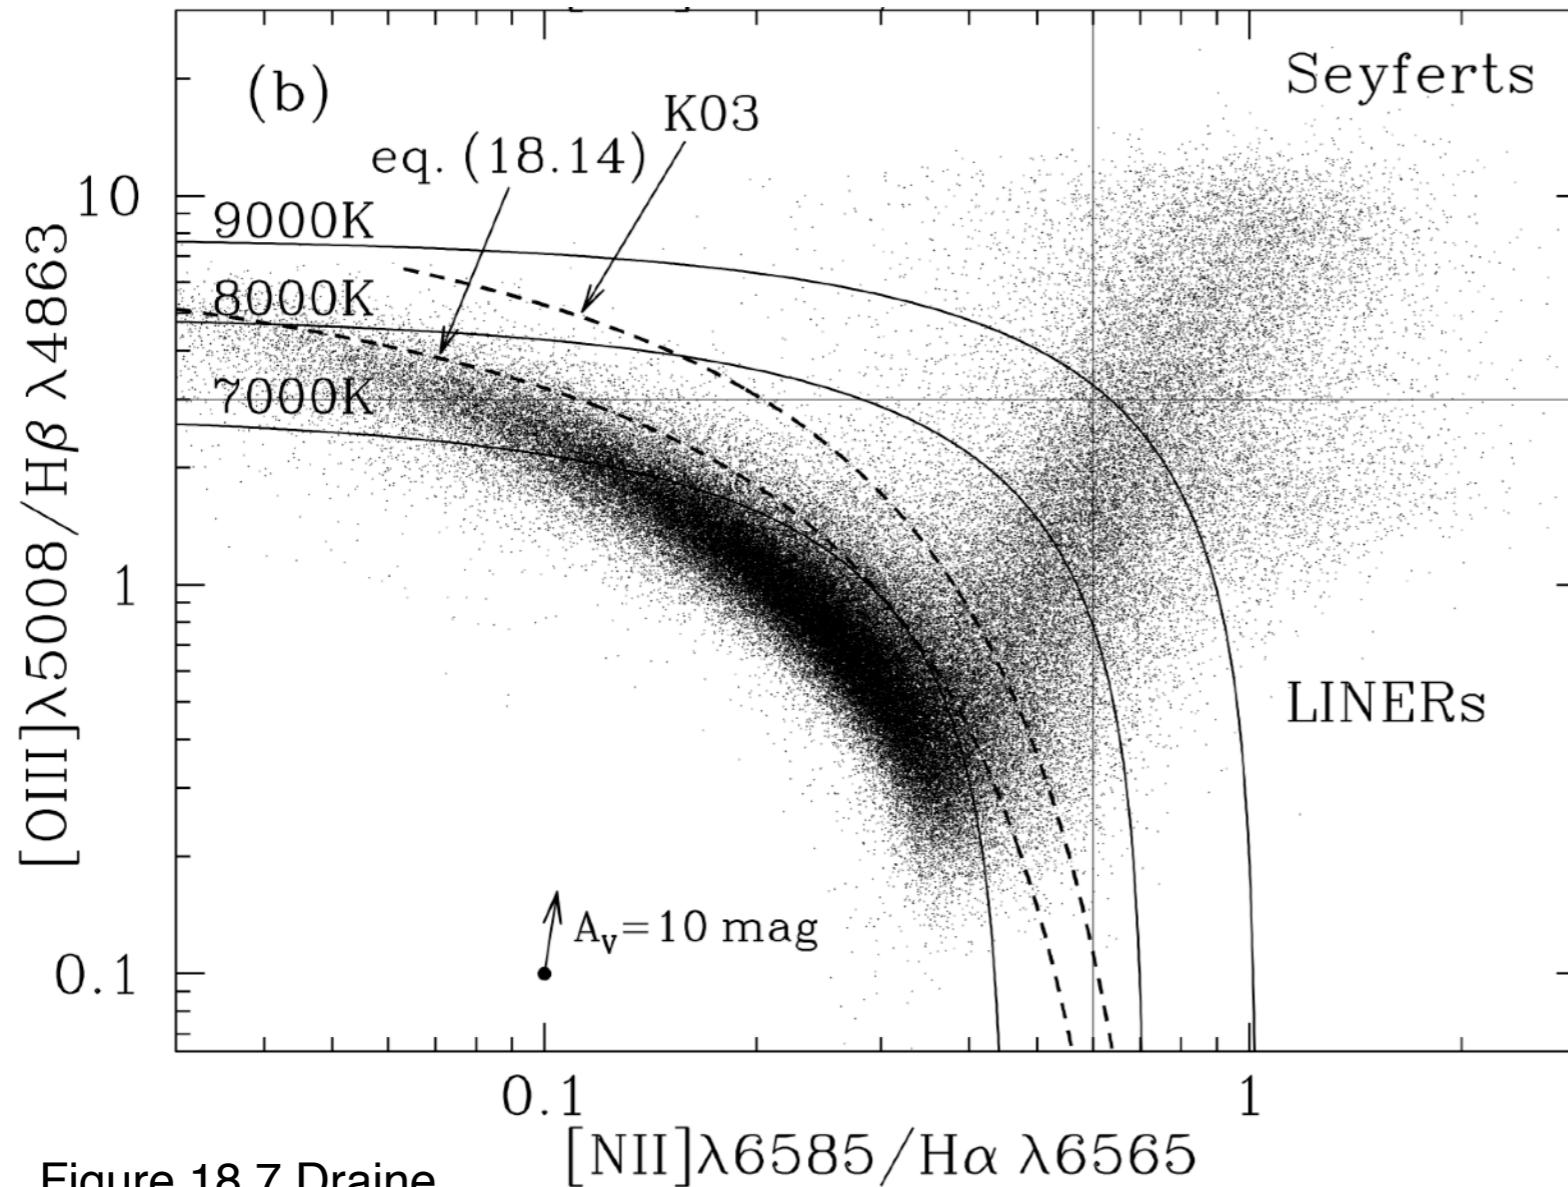

Figure 18.7 Draine

Flying seagull [Stasinska]

Photons from AGNs are harder than those from the massive stars that power H II regions.

They induce more heating, implying that optical collisionally excited lines will be brighter with respect to recombination lines than in the case of ionization by massive stars.

The heating by an AGN boosts the [N II] line and creates a clear separation of the two wings.

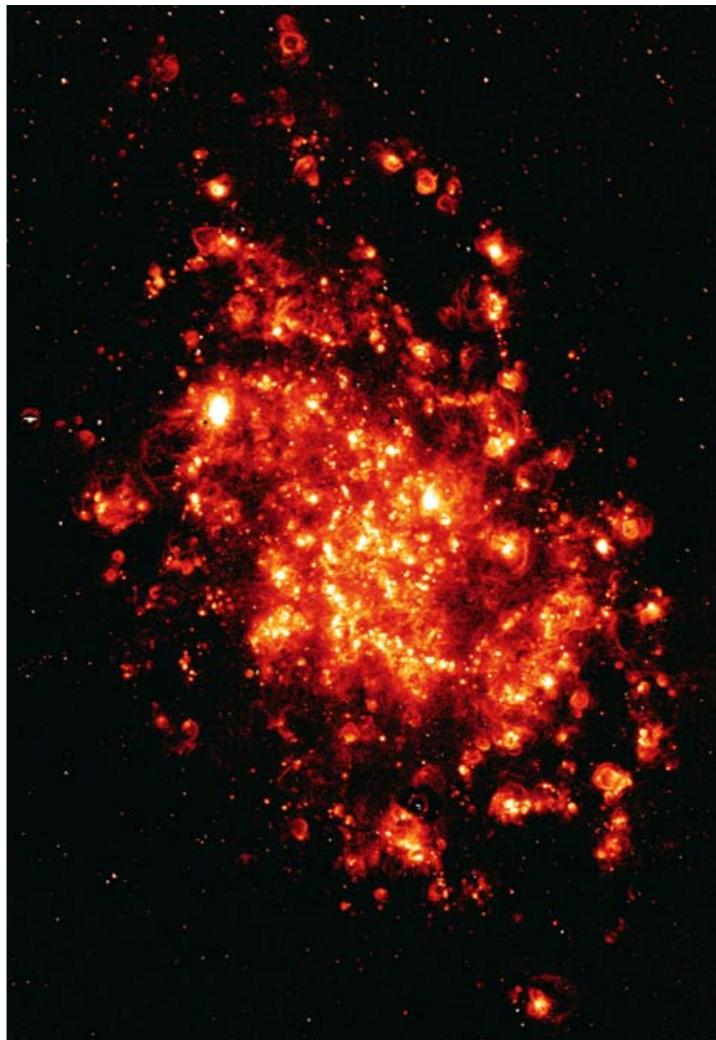

Warm Ionized Medium / Diffuse Ionized Gas

- ***Outside well-defined H II regions, the ISM is known to contain diffuse ionized gas***
 - which can originate either from leaks of ionized gas out of H II regions due to the champagne effect, or from ionization by the UV radiation of isolated hot stars, and perhaps from other mechanisms.
 - In our Galaxy, the DIG is known to contain much more mass than the HII regions. Its total mass is of the order of 1/3 of that of H I.

NGC 157

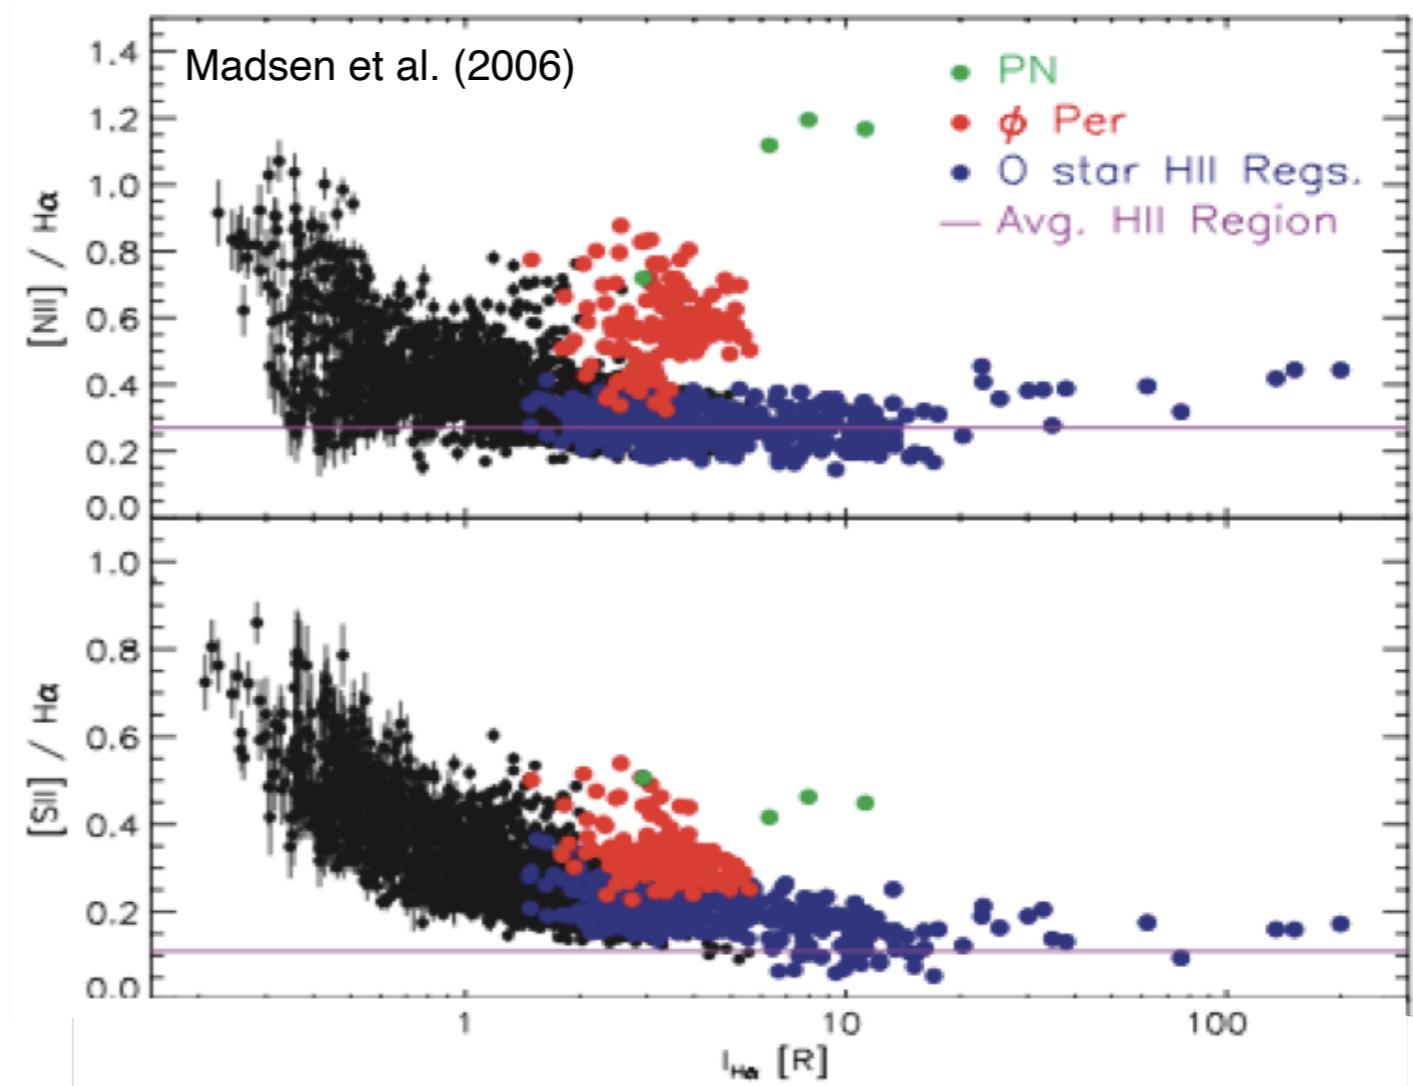

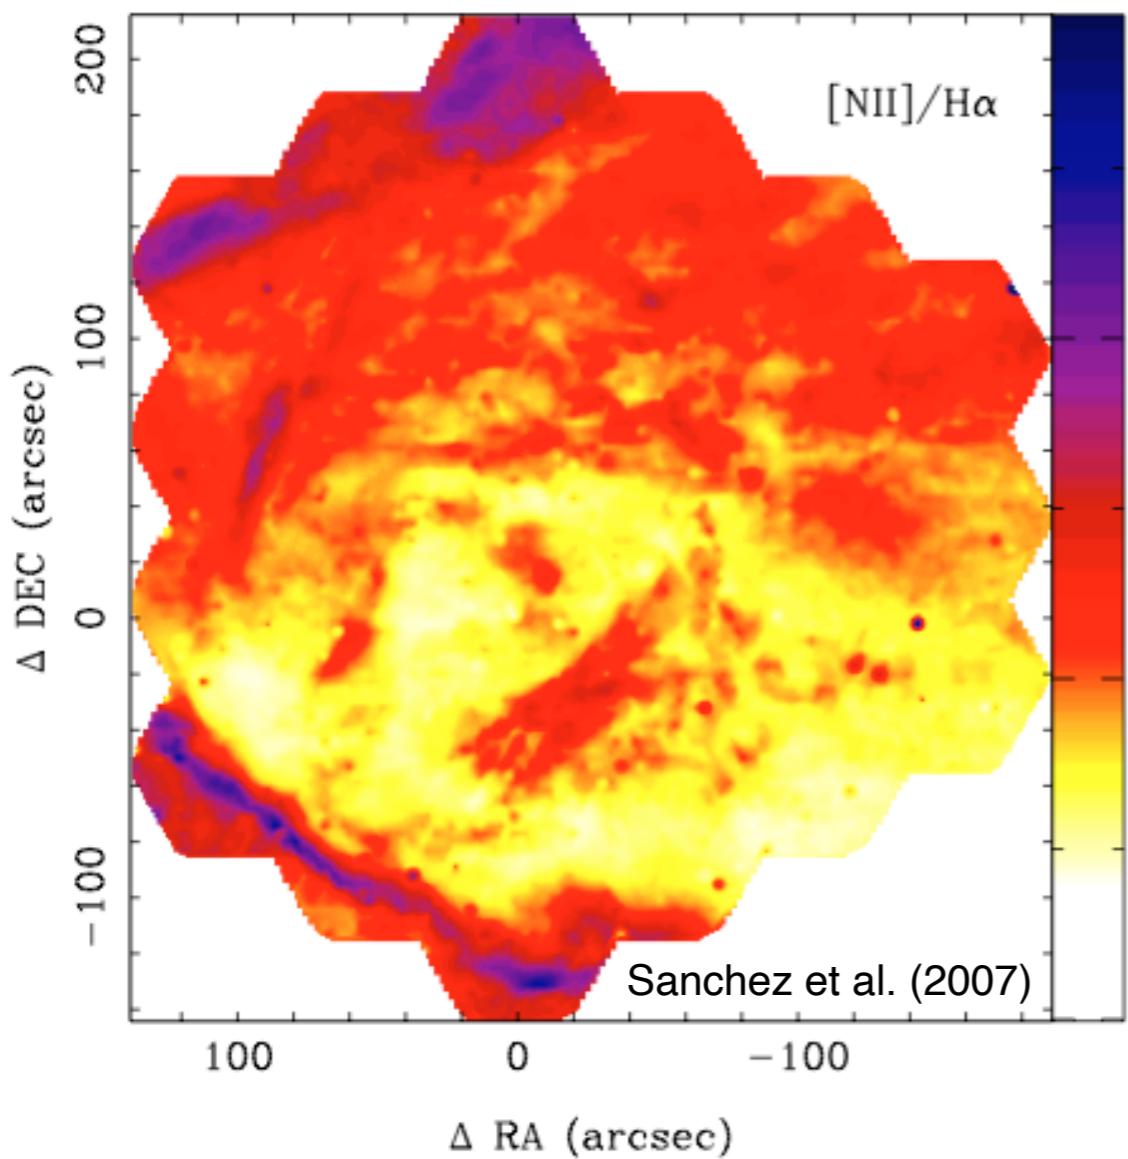

NGC 891 (Rand et al. 1998)

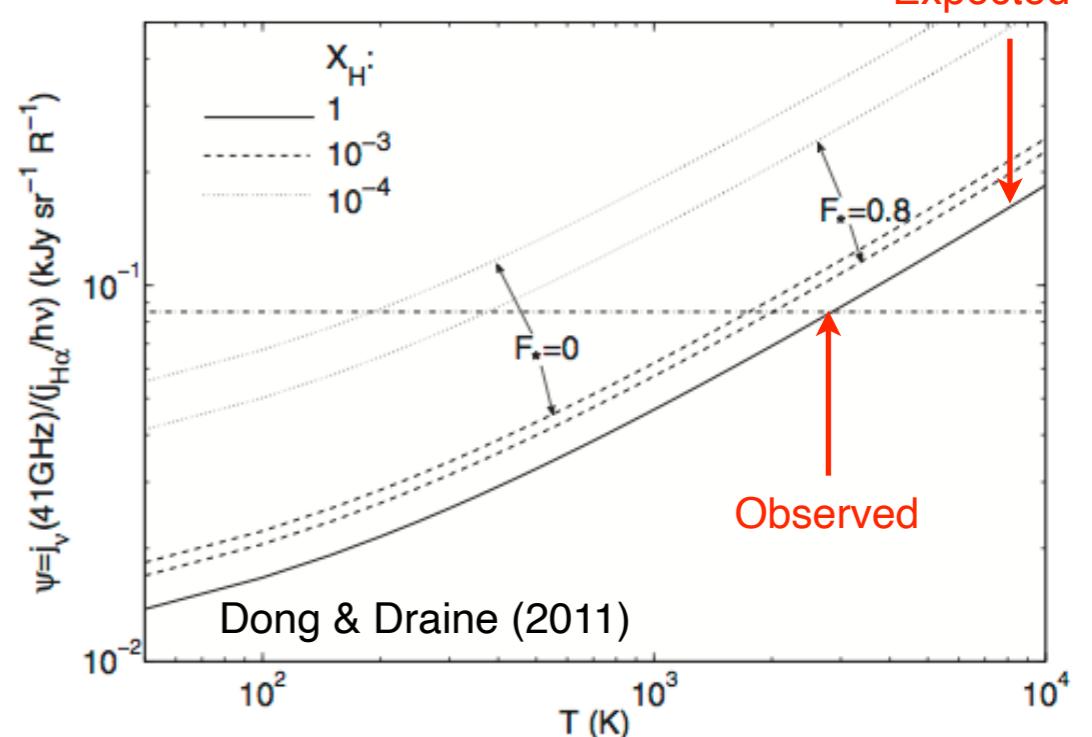

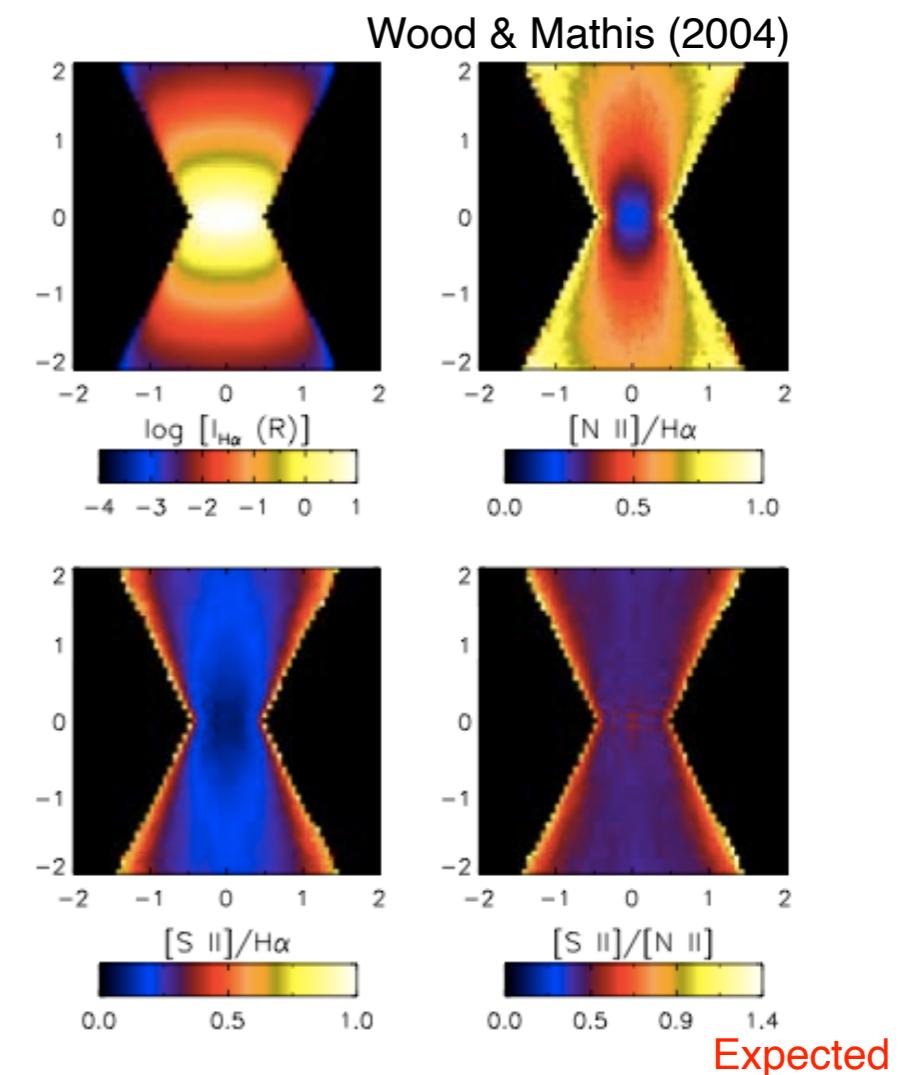

Optical Line Ratios

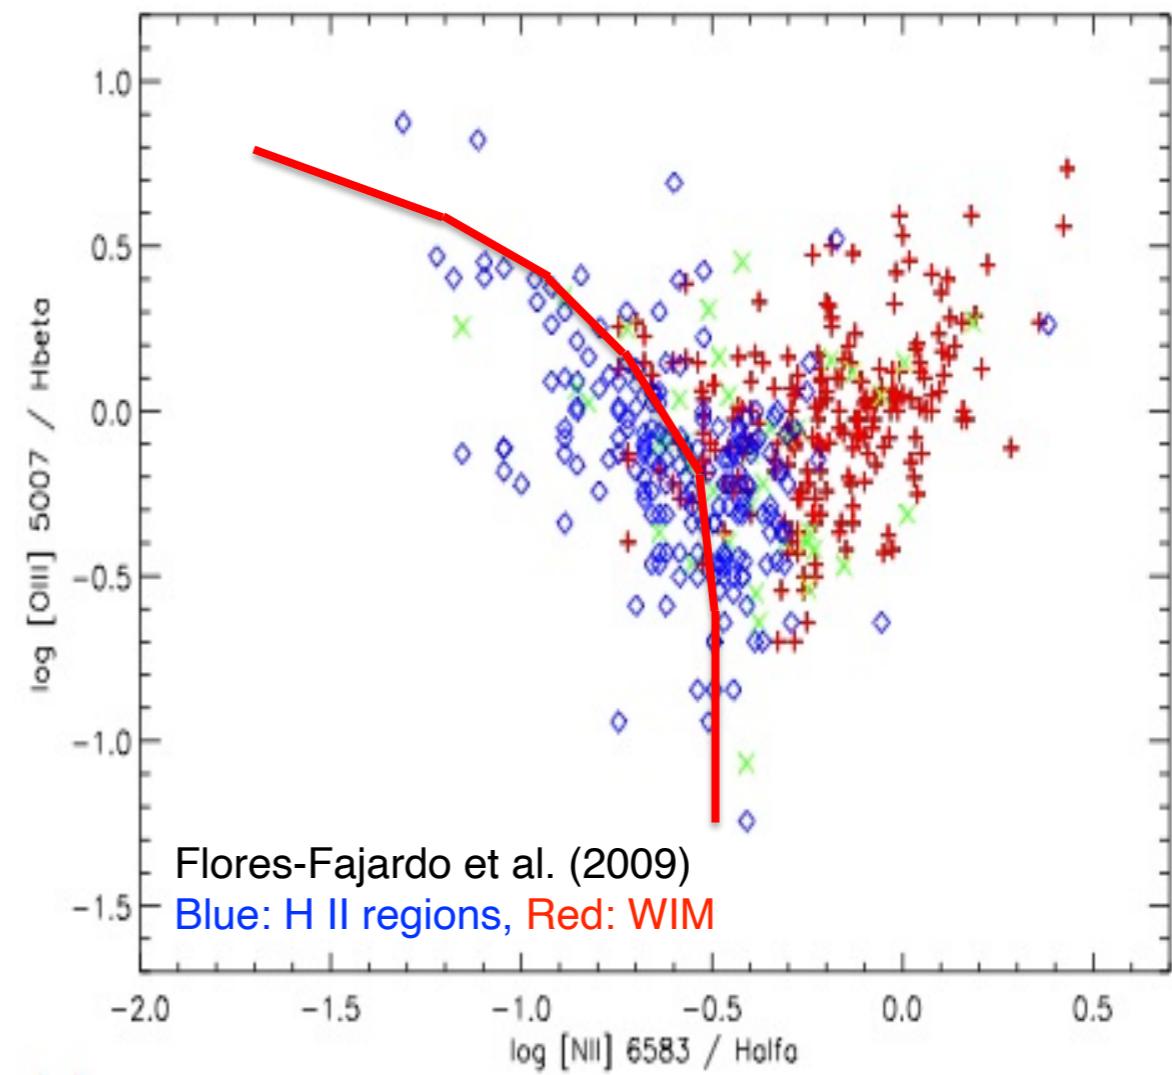

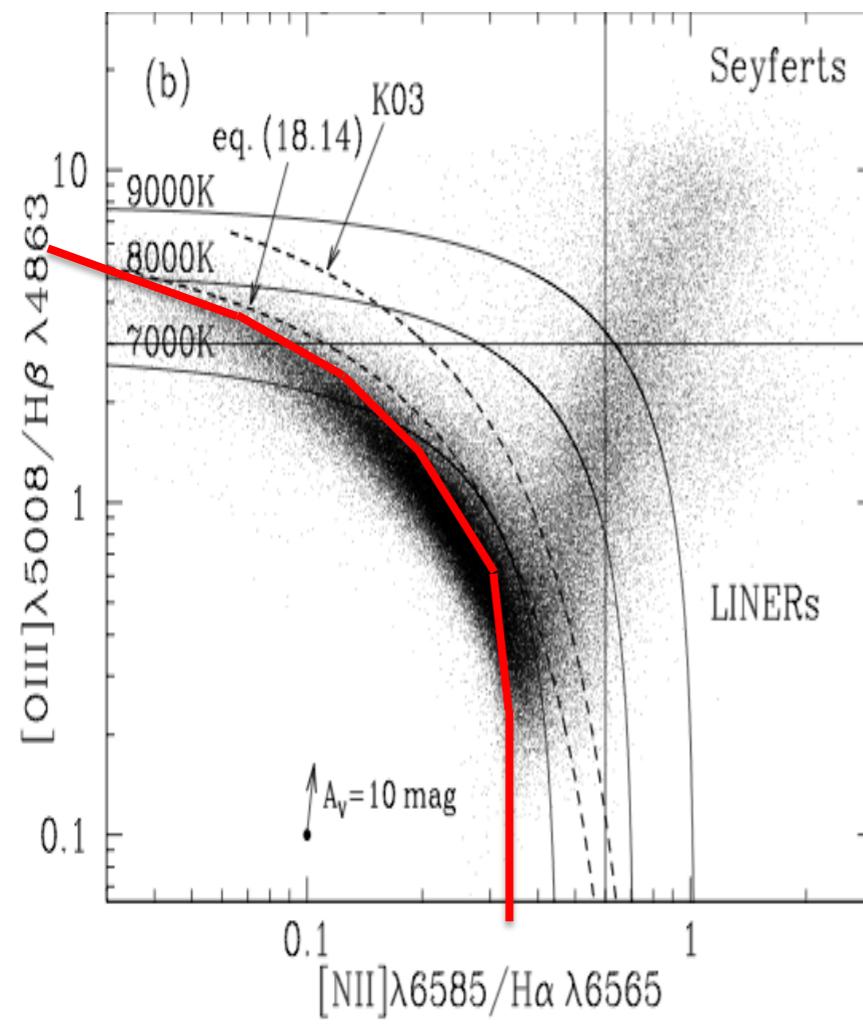

- $[\text{N II}] \lambda 6583/\text{H}\alpha$ and $[\text{S II}] \lambda 6716/\text{H}\alpha$ in the diffuse regions are generally higher than the ratios in bright H II regions.
 - $[\text{N II}]/\text{H}\alpha \approx 0.25$ and $[\text{S II}]/\text{H}\alpha \approx 0.1$ in bright H II regions
 - $[\text{N II}]/\text{H}\alpha \approx 0.3-0.6$ and $[\text{S II}]/\text{H}\alpha \approx 0.2-0.4$ in the diffuse ISM regions.

- Ionizing Mechanism
 - Only the O stars meet and surpass the power requirements to ionize the diffuse ISM.
 - Density-bounded (leaky) H II regions
 - ▶ Turbulent or clumpy morphology of the ISM
 - ▶ Existence of enormous, H I-free bubbles/holes surrounding the O stars
- However, this mechanism can not explain the free-free radio emission
 - The WMAP data shows that the observed ratio of free-free radio continuum to H α is at least twice smaller than the expected value.
 - Davies et al. (2006, 2009), Dobler & Finkbeiner (2008a,b), Gold et al. (2011)
- See Seon & Witt (2012), and Dong & Draine (2011) for the possibility of alternative explanations.

Heating source of the WIM

Detailed analyses of the line ratios $[N\text{ II}]/\text{H}\alpha$ and $[S\text{ II}]/\text{H}\alpha$ have been performed to obtain the temperature; it is found to be of the order of 8,000 K.

However, it is also known that WIM is being heated by additional sources. (see the above BPT diagram).

Dynamics of H II regions

- A new O star is presumably born within clouds of relatively dense cold gas. The appearance of a source of UV photons will have two effects.
 - First, the gas surrounding the new star will become ionized. Since the mean free path of an UV photon is very short in neutral hydrogen, the photons will be absorbed in a relatively thin surrounding shell of neutral hydrogen, producing new ionization. Thus the ionized and neutral gases are separated by an ionization front, which moves rapidly outward as more and more atoms become ionized by the stream of photons.
 - Second, the process increases the gas temperature from $\sim 10^2$ K to $\sim 10^4$ K, by a factor of about a hundred. the ionization process itself increases the number of gas particles, by a factor two. As a result, ***the pressure in the ionized gas is ~200 times greater than that in surrounding neutral material.*** This ionized gas cannot be confined and will expand. The ionized and neutral gas are set in motion.
 - Since the expansion velocity is likely to exceed the sound velocity in the surrounding H I region, a shock front may be expected to form, moving out through the neutral gas. The dynamical analysis of H II regions must consider the interactions between the ionization front and the shock front, together with the equations of motion of the gas behind the two fronts.
- This process is not the only way in which ISM is set in motion by means of interaction with stars.
 - There are effects produced by the very high speed continuous mass loss - a stellar wind.
 - Many massive stars terminate their existence in a violent explosive event - a supernova.

-
- Basic Assumptions:
 - Any disturbances to the cloud structure produced by the formation of a star are neglected. After a relatively short time ($< 10^5$ yr), the star reaches a static configuration in which it can remain for a much longer time ($> 3 \times 10^6$ yr). The stellar radiant energy output rate and the spectral distribution of the radiation are more or less constant during this phase. The star then produces Lyman continuum photons at a constant rate. Since the star formation time scale is so short, we may take the star to be ‘switched on’ instantaneously.
 - The gas around the star will be assumed to be at rest (in the frame of reference of the star).
 - The gas has initially assumed to be uniform in density and temperature.
 - Ionization front
 - The term “front” describes a more-or-less abrupt boundary between two regions of the ISM with very different properties.
 - An ionized nebula can be approximated as a region of highly ionized gas, separated from the surrounding neutral medium by a thin boundary region, of thickness $\lambda_{\text{mfp}} \sim 0.002 \text{ pc}$. Thus, an H II region is surrounded by an ionization front.

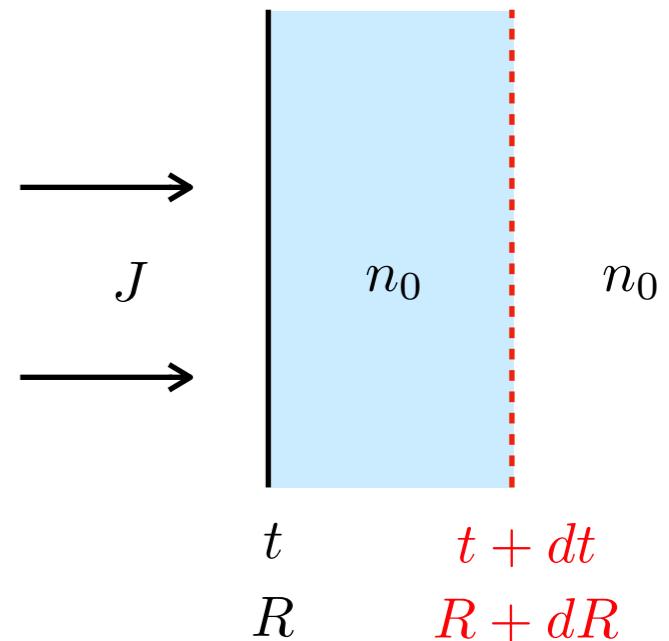

The velocity of the ionization front

- Suppose that at time t the ionization front is located at a distance R from the star and at time $t + dt$ it is at a distance $R + dR$.
 - Let n_0 = number density of the undisturbed neutral hydrogen
 J = number of Lyman continuum photons incident normally on unit area of the ionization front per unit time.
- Ionization balance at the ionization front:** While the ionization front moves from R to $R + dR$, the photons will ionize all the neutral atoms lying between these two positions ($R, R + dR$).
- We assume that only one photon is needed to ionize each atom as the front moves the distance dR . In other words, no recombination occurs within the distance interval dR . For unit area of the ionization front, the following relation must be satisfied:

$$J \Delta A dt = n_0 \Delta A dR$$

- Then, the velocity of the ionization front (in a fixed frame of reference) is:

$$\frac{dR}{dt} = \frac{J}{n_0}$$

The initial stage of evolution of an ionized region

- Suppose that the UV source has been suddenly turned on.
 - Ionization balance for the ionized region:*** We consider two factors:
 - The radiation field at the ionization front is diluted because of the spherical geometry.
 - Recombination takes place continuously inside the ionized region, and some of the UV photons produced by the central source must go to reionize the atoms that have recombined.

$$Q_0 = (4\pi R^2) J + \left(\frac{4\pi}{3} R^3\right) \alpha_B n_e n_p$$

- Inside the ionized sphere, the fractional ionization is near unity. Thus, $n_e = n_p = n_0$. Using this condition, we obtain an equation for the expansion velocity of the ionization front.

$$\frac{J}{n_0} = \frac{dR}{dt} = \frac{Q_0}{4\pi R^2 n_0} - \frac{1}{3} R n_0 \alpha_B$$

- Let's define the following dimensionless quantities:

$$\rho \equiv R/R_s \quad \text{where } R_s \equiv \left(\frac{3}{4\pi} \frac{Q_0}{\alpha_B n_0^2} \right)^{1/3}$$

$$\tau \equiv t/t_{\text{rec}} \quad \text{where } t_{\text{rec}} \equiv \frac{1}{\alpha_B n_0}$$

Then, the equation in dimensionless form is

$$\frac{d\rho}{d\tau} = \frac{1}{3} \left(\frac{1}{\rho^2} - \rho \right)$$

- ▶ The equation can be written:

$$\frac{d\rho}{d\tau} = \frac{1}{3} \left(\frac{1}{\rho^2} - \rho \right) \rightarrow \frac{d\rho^3}{d\tau} = 1 - \rho^3$$

- ▶ Its solution is

$$\rho^3 = 1 - e^{-\tau}$$

$$R(t) = R_s \left(1 - e^{-t/t_{\text{rec}}} \right)^{1/3}$$

$$\begin{aligned} \frac{dx}{d\tau} + x &= 1 \\ e^\tau \frac{dx}{d\tau} + e^\tau x &= e^\tau \\ \frac{d(e^\tau x)}{d\tau} &= e^\tau \end{aligned} \quad \boxed{\begin{aligned} e^\tau x &= \int_0^\tau e^{\tau'} d\tau' = e^\tau - 1 \\ x &= 1 - e^{-\tau} \end{aligned}}$$

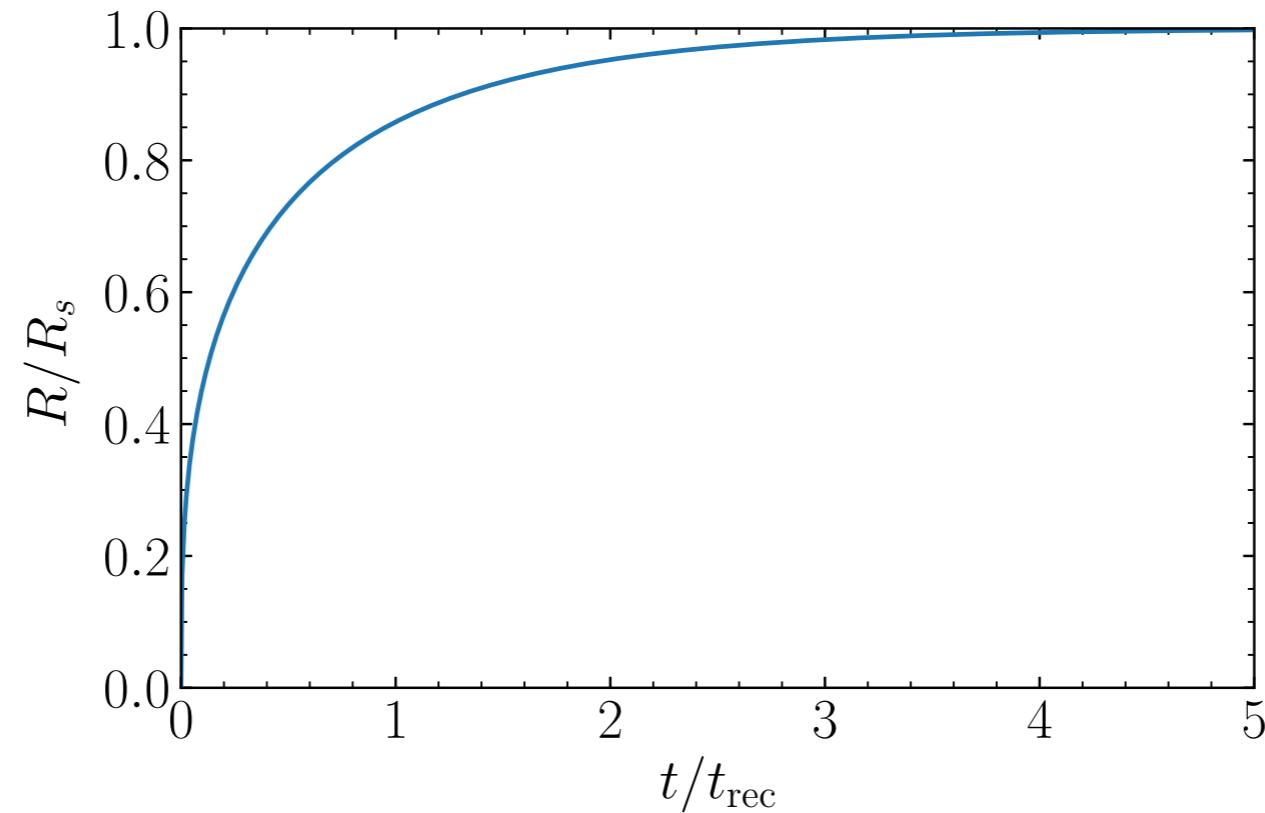

- Scale Parameters:
 - The time scale introduced is the recombination time scale:

$$t_{\text{rec}} \equiv \frac{1}{\alpha_B n_0} \approx 4000 \text{ yr} \left(\frac{\alpha_B}{2.6 \times 10^{-3} \text{ cm}^3 \text{ s}^{-1}} \right)^{-1} \left(\frac{n_0}{30 \text{ cm}^{-3}} \right)^{-1}$$

the length scale introduced is the Strömgren radius:

$$R_s \equiv \left(\frac{3}{4\pi} \frac{Q_0}{\alpha_B n_0^2} \right)^{1/3} \approx 7 \text{ pc} \left(\frac{Q_0}{10^{49} \text{ s}^{-1}} \right)^{1/3} \left(\frac{\alpha_B}{2.6 \times 10^{-3} \text{ cm}^3 \text{ s}^{-1}} \right)^{-1/3} \left(\frac{n_0}{30 \text{ cm}^{-3}} \right)^{-2/3}$$

-
- Hence, the time required to create a Strömgren sphere after turning on a hot star is an order of ~ 4000 yr. This is also the time it takes the ionized Strömgren sphere to revert to neutral gas after the central UV source has been turned off.

- At times $t \gg t_{\text{rec}} \sim 4000$ yr , the gas medium will be fully ionized with radius $R \sim R_s \sim 7$ pc, surrounded by a partially ionized boundary of thickness $\sim \lambda_{\text{mfp}} = (n_{\text{H}}\sigma_{\text{pi}})^{-1} \sim 0.002$ pc $\ll R_s$.

- We can compute the ***rate of expansion of the ionization front***:

$$\frac{dR}{dt} = \frac{R_s}{3t_{\text{rec}}} \frac{e^{-t/t_{\text{rec}}}}{(1 - e^{-t/t_{\text{rec}}})^{2/3}}$$

where the characteristic expansion velocity is

$$v_* \equiv \frac{R_s}{3t_{\text{rec}}} \simeq 560 \text{ km s}^{-1} \left(\frac{Q_0}{10^{49} \text{ s}^{-1}} \right)^{1/3} \left(\frac{n_0}{30 \text{ cm}^{-3}} \right)^{1/3}$$

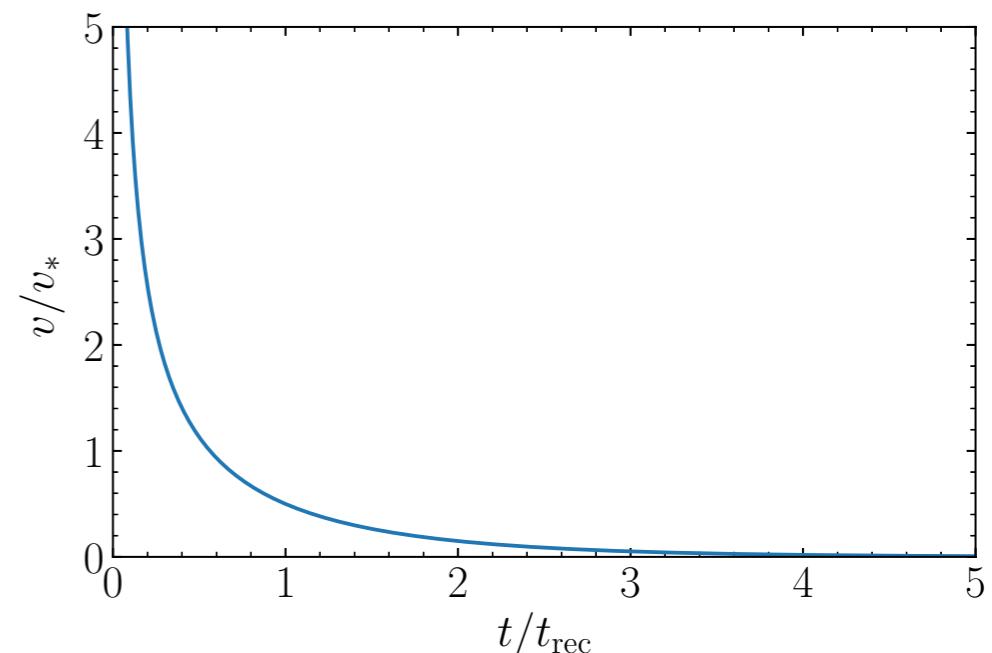

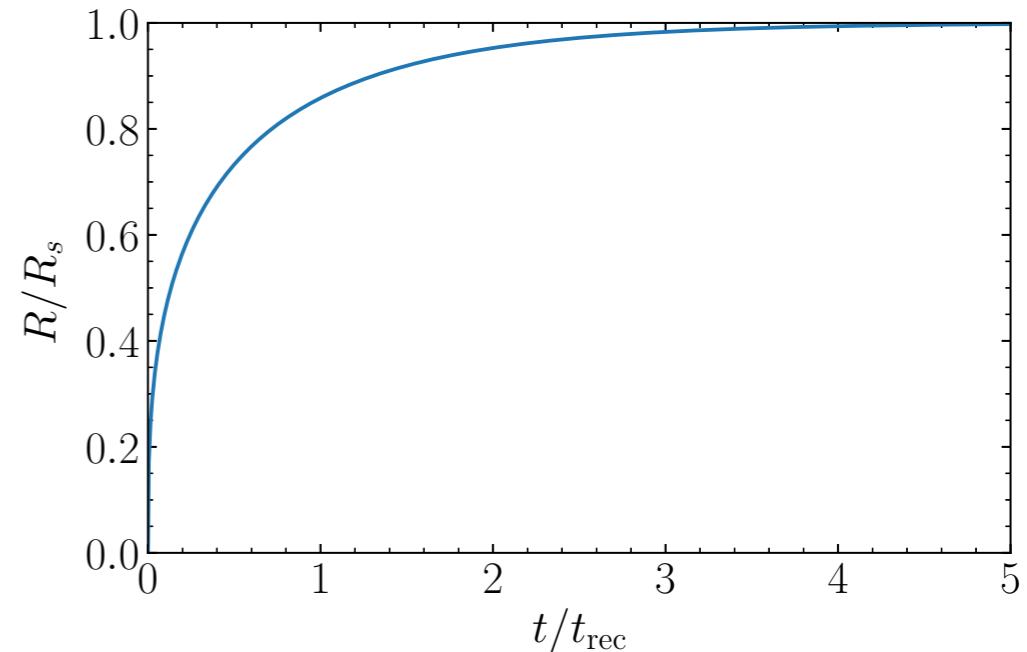

This is much larger than the sonic speed $c_s \approx 1 \text{ km s}^{-1}$ in the neutral medium as well as $c_s \approx 10 \text{ km s}^{-1}$ in the ionized medium.

- The expansion speed of the ionization front at two limits:

$$\frac{dR}{dt} \approx \frac{R_s}{3t_{\text{rec}}} \left(\frac{t}{t_{\text{rec}}} \right)^{-2/3} \quad \text{for } t \ll t_{\text{rec}}$$

$$\frac{dR}{dt} \approx \frac{R_s}{3t_{\text{rec}}} e^{-t/t_{\text{rec}}} \quad \text{for } t \gg t_{\text{rec}}$$

Note that the expansion speed diverges at $t = 0$.

-
- The ionization front will initially expand supersonically. When will the ionization front expand at subsonic speeds?

$$\frac{dR}{dt} = \frac{R_s}{3t_{\text{rec}}} e^{-t/t_{\text{rec}}} \lesssim c_i \quad c_i \approx 13 \text{ km s}^{-1} \quad \text{sound speed in the ionized medium}$$

$$t \lesssim t_{\text{sonic}} \equiv t_{\text{rec}} \ln \left(\frac{R_s}{3t_{\text{rec}}} \frac{1}{c_i} \right) \approx 3.8t_{\text{rec}} \simeq 15,000 \text{ yr}$$

- At this time, the ionization front will have a size of:

$$R(t = t_{\text{sonic}}) = R_s (1 - e^{-3.8})^{1/3} = 0.9925 R_s$$

- The ionization front will expand at a supersonic velocity until $t \approx t_{\text{sonic}}$ ($\sim 15,000$ yr). By that time, the ionized sphere has reached a radius $R \sim 0.99 R_s$ and then it starts to expand at subsonic speed.
- At $t = R_s/c_s \sim 0.5 \text{ Myr}$, the gas starts to flow outward as a result of the pressure gradient that has build up.

The final stage of evolution of an ionized region

- Although the ionized sphere approaches ionization equilibrium at $t \gtrsim t_{\text{rec}}$, it would be still far from pressure equilibrium.
 - Outside the ionized zone, it will be embedded in the cold neutral medium with a temperature $T \sim 100$ K.
 - Inside the sphere, the heating and cooling processes yield a temperature of $T \sim 10000$ K.
 - Also, the density of particles inside the ionized sphere will double when the hydrogen is ionized.
 - Thus, the pressure inside the sphere will be ~ 200 times higher than the pressure outside, meaning that the ionized gas will begin to expand.
 - The ionized gas expands as long as it has a higher pressure than its surroundings. This expansion produces a shock and will cease when the hot ionized gas reaches pressure equilibrium with the surrounding cold neutral gas.
- The condition of final pressure equilibrium can be written in the form:

$$2n_f k T_i = n_0 k T_n$$

n_f = number density of the ionized hydrogen.

T_i and T_n = temperatures of the ionized and neutral gas, typically $T_i = 10^4$ K, $T_n = 10^2$ K .

-
- The ionized gas sphere must still absorb all the stellar UV photons. Thus,

$$Q_0 = \frac{4}{3}\pi R_f^3 n_f^2 \alpha_B$$

Here, R_f is the final radius of the ionized gas sphere. From the pressure equilibrium condition, we obtain the final size:

$$n_f = (T_n/2T_i)n_0 \approx 0.005n_0 \quad \rightarrow \quad R_f = (2T_i/T_n)^{2/3}R_{s0} \approx 34R_{s0}$$

- The ratio of the mass of gas finally ionized to that contained within the initial Stromgren sphere is:

$$\frac{M_f}{M_s} = \frac{R_f^3 n_f}{R_{s0}^3 n_0} = \frac{2T_i}{T_n} \approx 200$$

- This indicates that the initial Stromgren sphere contains only a very small fraction of the material which, in principle, a star could ultimately ionize.

The intermediate stage of evolution of an ionized region

- Before the pressure equilibrium is established, the gas density and temperature will be

$$n_i \approx 2n_0 > n_f \quad \text{and} \quad T_i = 10^4 \text{ K}$$

- Then the isothermal sound speeds of the ionized gas and neutral gas are, respectively:

$$c_i^2 = \frac{P_i}{\rho_i} \approx \frac{2n_0 k T_i}{n_0 m_H} \quad c_n^2 = \frac{P_n}{\rho_n} = \frac{n_0 k T_n}{n_0 m_H}$$

$$\frac{c_i}{c_n} = \left(\frac{n_i T_i}{n_0 T_n} \right)^{1/2} \approx \sqrt{200} = 14.14$$

- The sound speed of the ionized gas is much larger than that of the neutral gas.
 - The ionized gas has a higher pressure and thus plays the role of a piston and pushes a shock wave into the neutral gas. *The expansion speed of the ionized gas is originally equal to about c_i , which is highly supersonic with respect to the sound speed in the neutral gas.*
 - Note also that, at $t \gtrsim t_{\text{sonic}} \approx 3.8t_{\text{rec}}$, the expansion speed of ionized gas is larger than that of the ionization front.

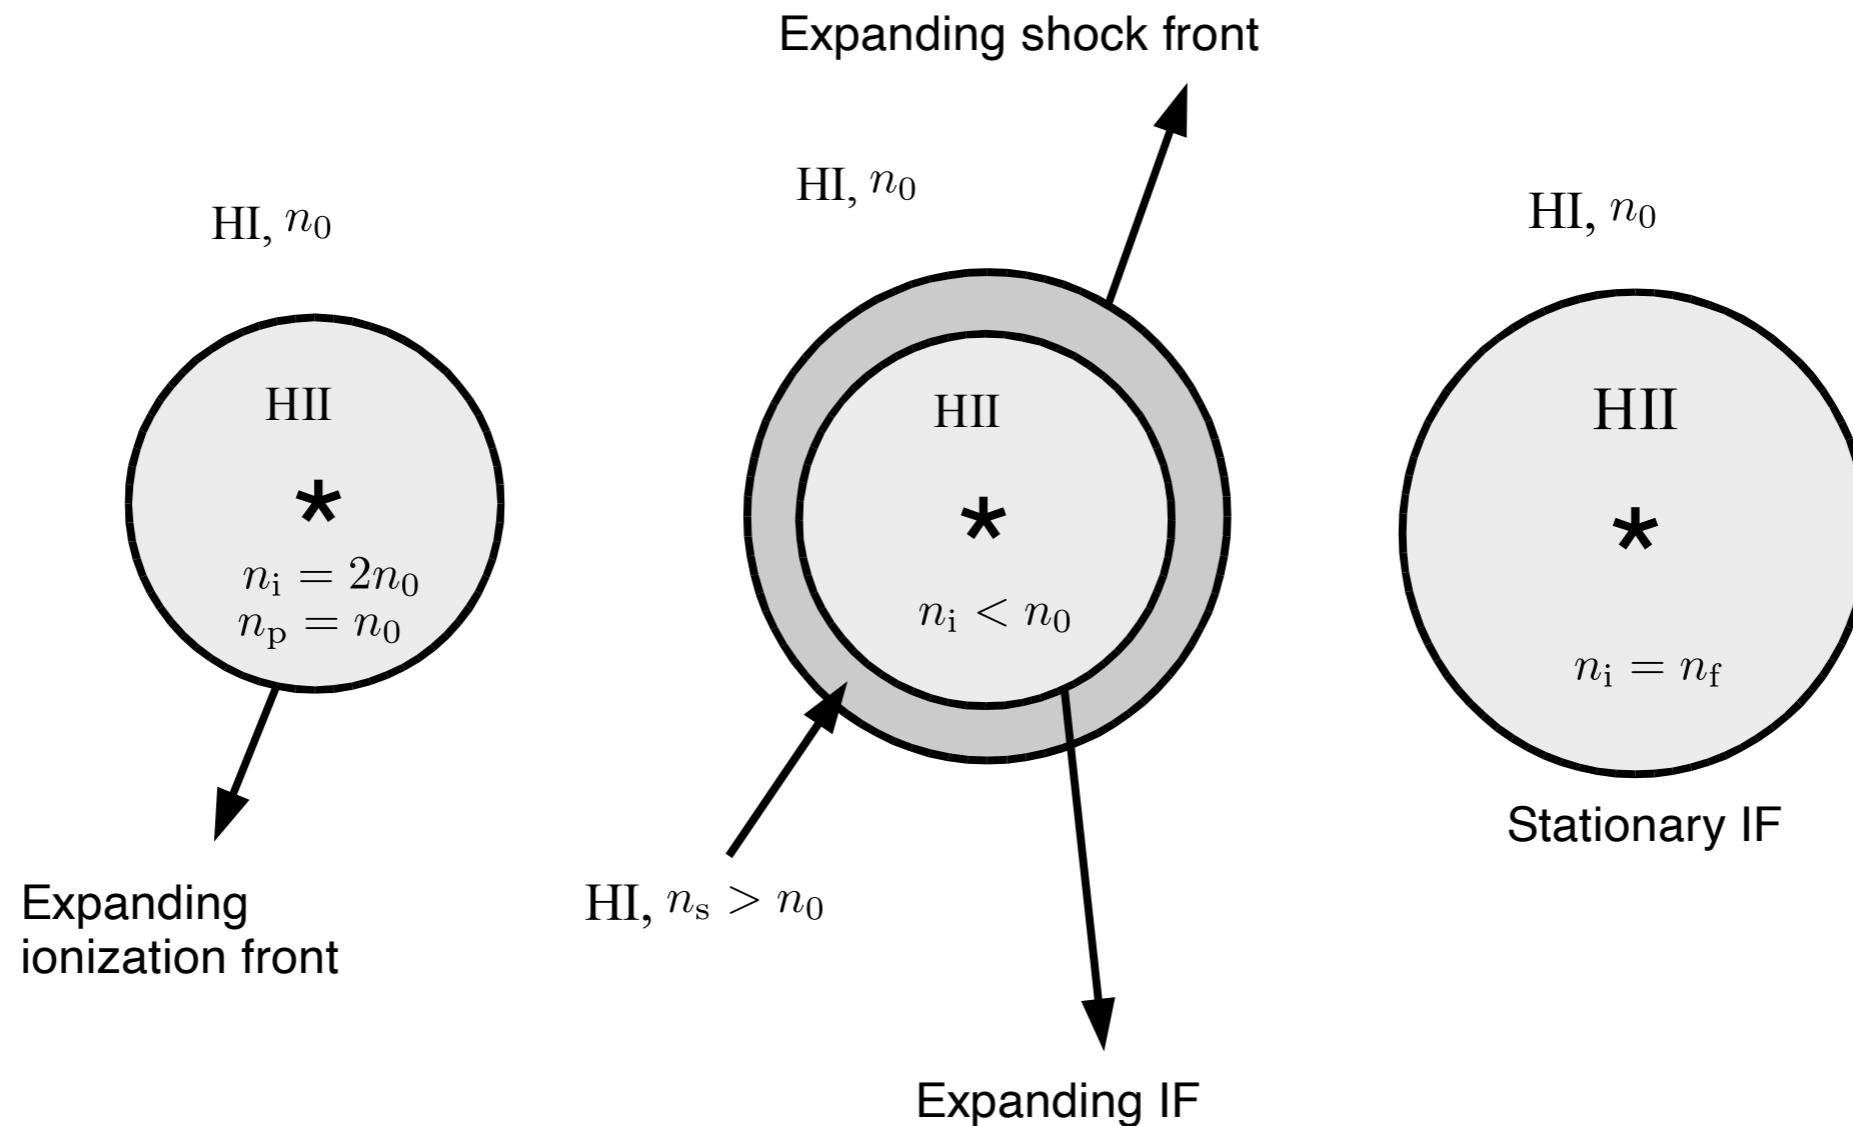

$$\frac{dR}{dt} > c_i \text{ at } t \lesssim t_{\text{sonic}}$$

initial stage

$$\longrightarrow \quad \frac{dR}{dt} \approx c_i \text{ at } t \approx t_{\text{sonic}}$$

intermediate stage

$$\frac{dR}{dt} < c_i \text{ at } t \gtrsim t_{\text{sonic}}$$

Evolutionary scheme of an expanding H II region. (a) The initial stage, (b) expansion with a shock in the neutral gas, (c) the final equilibrium state.

[Figure 7.2 Dyson]

-
- Sound crossing time
 - The ionized region will likely be overpressure relative to its surroundings, in which case it will expand on the sound crossing time.
 - The isothermal sound speed in fully ionized hydrogen is

$$c_s = (2kT/m_{\text{H}})^{1/2} = 13(T/10^4 \text{ K})^{1/2} \text{ km s}^{-1} \quad p = (n_{\text{HI}} + n_e)kT = 2n_{\text{H}}kT$$

- The time for a pressure wave to propagate a distance equal to Strömgren radius is
- $$t_{\text{sound}} = \frac{R_s}{c_s} \approx 2.39 \times 10^5 \frac{Q_0/10^{49} \text{ s}^{-1}}{(n/10^2 \text{ cm}^{-3})^{2/3}} \text{ [yr]}$$
- This is about a hundred times longer than the recombination time (timescale of the expanding ionization front).

Ionization Front: Jump Condition

- Low density gas, like that of the ISM, can be treated as an ideal gas, with no viscosity with a pressure given by the ideal gas law:

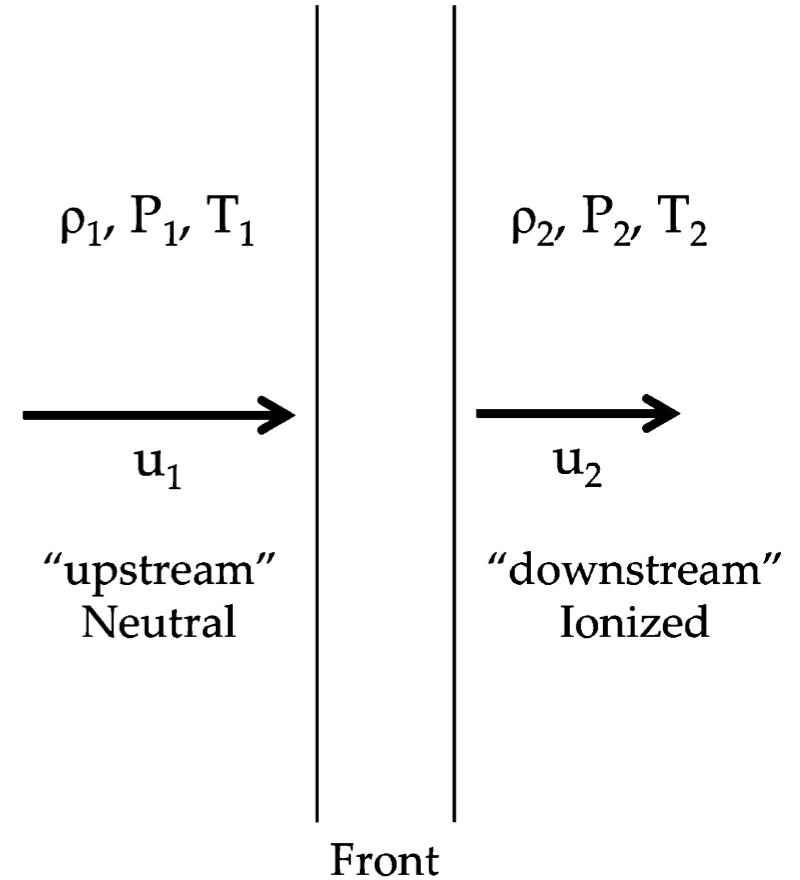

$$P = \frac{\rho k T}{m}$$

ρ = mass density, T = temperature,
 m = mean molecular mass

ρ, P, T, u = density, pressure, temperature, and bulk velocity

- Let's consider a small patch of the ionization front between the interior of an H II region and its exterior.

- If the patch is small compared to the ionization front's radius of curvature, then we can treat the ionization front as if it has **plane parallel** symmetry.
- It is convenient to use **a frame of reference in which the ionization front is stationary**; in this frame, the bulk velocity u_1 of the neutral gas points toward the ionization front. The bulk velocity u_2 of the ionized gas points away from the ionization front.

Gas Dynamics

- Assumption for hydrodynamics:
 - particle mean free path \ll size of the region
 - We will describe the equations for conservation of mass, momentum and energy, in 1D space.
- Conservation equations
 - Mass conservation (continuity equation)
 - ▶ mass within a volume $dV = \rho dV/dA = \rho dx$ (per unit area)
 - ▶ no sources or sinks of material within dV

$$\begin{aligned}\frac{\partial}{\partial t}(\rho dx) &= \overbrace{\rho u}^{\text{incoming}} - \overbrace{(\rho + d\rho)(u + du)}^{\text{outgoing}} \\ &= -(\rho du + ud\rho + \cancel{d\rho du})\end{aligned}$$

$$\frac{\partial \rho}{\partial t} = -\frac{\partial(\rho u)}{\partial x}$$

- ▶ Mass loss and gain terms could be added in the right-hand side.

- Momentum conservation (Euler's equation)
 - ▶ momentum within dV (per unit area) = $(\rho dV)u/dA = \rho dx u$
 - ▶ = change of momentum due to fluid flow and gas pressure acting on the surface of dV

$$\begin{aligned}\frac{\partial}{\partial t}(\rho u dx) &= \overbrace{\rho u^2}^{\text{incoming}} - \overbrace{(\rho + d\rho)(u + du)^2}^{\text{outgoing}} + \overbrace{P}^{\text{incoming}} - \overbrace{P + dP}^{\text{outgoing}} \\ &= \rho u^2 - \left(\rho u^2 + 2\rho u du + \cancel{\rho du^2} + u^2 d\rho + \cancel{2ud\rho du} + \cancel{d\rho du^2} \right) - dP\end{aligned}$$

$$\begin{aligned}\frac{\partial}{\partial t}(\rho u) &= -2\rho u \frac{\partial u}{\partial x} - u^2 \frac{\partial \rho}{\partial x} - \frac{\partial P}{\partial x} \\ \rho \frac{\partial u}{\partial t} + u \frac{\partial \rho}{\partial t} &= -\rho u \frac{\partial u}{\partial x} - u \left(\rho \frac{\partial u}{\partial x} + u \frac{\partial \rho}{\partial x} \right) - \frac{\partial P}{\partial x}\end{aligned}$$

$$\begin{aligned}\frac{\partial}{\partial t}(\rho u) &= -2\rho u \frac{\partial u}{\partial x} - u^2 \frac{\partial \rho}{\partial x} - \frac{\partial P}{\partial x} \\ &= -\frac{\partial}{\partial x}(\rho u^2) - \frac{\partial P}{\partial x}\end{aligned}$$

or

Using mass conservation, $\frac{\partial u}{\partial t} = -\frac{\partial(\rho u)}{\partial x}$

$$\rho \frac{\partial u}{\partial t} = -\rho u \frac{\partial u}{\partial x} - \frac{\partial P}{\partial x}$$

$$\frac{\partial}{\partial t}(\rho u) = -\frac{\partial}{\partial x} (\rho u^2 + P)$$

- ▶ Further terms could be added in the right-hand side, accounting for forces due to gravity, magnetic fields, radiation field, and viscosity.

-
- Let's consider a steady state solution.
 - We have seen that the speed of the ionization front surrounding a Stromgren sphere changes with time. However, the steady state solution gives us some intuition about the behavior of ionization fronts in general.
 - Then, the mass conservation and momentum conservation equation becomes:

$$\frac{d}{dx} (\rho u) = 0 \quad \frac{d}{dx} (\rho u^2 + P) = 0$$

- Let subscript 1 denote fluid variables in the neutral gas ahead of the I-front, and subscript 2 denotes fluid variables in the ionizing gas behind the I-front. Integrating these equations across the ionization front, we obtain:

$$\rho_1 u_1 = \rho_2 u_2$$

$$\rho_1 u_1^2 + P_1 = \rho_2 u_2^2 + P_2$$

-
- The number of H atoms flowing through the ionization front per unit area per second must equal to J , the corresponding number of ionizing photons reaching the front. Hence, the equation becomes

$$\rho_1 u_1 = \rho_2 u_2 = m_i J \quad \text{Here, } u_1 = \frac{dR}{dt} = \frac{J}{n_0}, \quad \rho_1 = m_i n_0$$

where m_i is the mean mass of the gas per newly created positive ion ($m_i = m_H$ in a pure hydrogen gas). We may also write the equation of momentum conservation using the isothermal sound speeds:

$$\rho_1 (u_1^2 + c_1^2) = \rho_2 (u_2^2 + c_2^2) \quad c_s^2 = \frac{P}{\rho} \text{ for isothermal gas}$$

- In the discussion, we will consider a hydrogen gas.

$$c_1 = \left(\frac{kT_1}{m_H} \right)^{1/2} = 0.91 \text{ km s}^{-1} \left(\frac{T_1}{100 \text{ K}} \right)^{1/2} \quad \text{neutral hydrogen gas}$$

$$c_2 = \left(\frac{2kT_2}{m_H} \right)^{1/2} = 12.9 \text{ km s}^{-1} \left(\frac{T_2}{10^4 \text{ K}} \right)^{1/2} \quad \text{fully ionized gas}$$

Here, the number density of particles is $2n_H$ in a fully-ionized hydrogen gas (downstream) and thus the factor 2 in c_2 .

- In summary, the equations are

$$\begin{aligned}\rho_1 u_1 &= \rho_2 u_2 = m_i J \\ \rho_1 (u_1^2 + c_1^2) &= \rho_2 (u_2^2 + c_2^2)\end{aligned}$$

- We assume that ρ_1 and u_1 are known, and we seek to solve for the unknown ρ_2 and u_2 . We obtain a simple quadratic equation for $x \equiv \rho_1/\rho_2 = u_2/u_1$.

$$\begin{aligned}\frac{\rho_1}{\rho_2} (u_1^2 + c_1^2) &= \left(\frac{\rho_1}{\rho_2}\right)^2 u_1^2 + c_2^2 \\ u_1^2 x^2 - (u_1^2 + c_1^2)x + c_2^2 &= 0 \quad \longrightarrow \quad x = \frac{1}{2u_1^2} \left[(u_1^2 + c_1^2) \pm \sqrt{(u_1^2 + c_1^2)^2 - 4u_1^2 c_2^2} \right]\end{aligned}$$

Then, the ratios between densities and velocities are:

$$\frac{u_2}{u_1} = \frac{\rho_1}{\rho_2} = \frac{1}{2u_1^2} \left[(u_1^2 + c_1^2) \pm \sqrt{(u_1^2 + c_1^2)^2 - 4u_1^2 c_2^2} \right]$$

$$\frac{\rho_2}{\rho_1} = \frac{u_1}{u_2} = \frac{1}{2c_2^2} \left[(u_1^2 + c_1^2) \mp \sqrt{(u_1^2 + c_1^2)^2 - 4u_1^2 c_2^2} \right]$$

-
- The roots are real if and only if

$$\begin{aligned} f(u_1) &\equiv (u_1^2 + c_1^2)^2 - 4u_1^2 c_2^2 \\ &= (u_1^2 + c_1^2 + 2u_1 c_2)(u_1^2 + c_1^2 - 2u_1 c_2) \geq 0 \end{aligned}$$

This requires:

$$\begin{aligned} u_1^2 + c_1^2 - 2u_1 c_2 &\geq 0 \\ \left[u_1 - \left(c_2 + \sqrt{c_2^2 - c_1^2} \right) \right] \left[u_1 - \left(c_2 - \sqrt{c_2^2 - c_1^2} \right) \right] &\geq 0 \end{aligned}$$

Therefore,

$$u_1 \geq u_R \equiv c_2 + \sqrt{c_2^2 - c_1^2} \quad \text{or} \quad u_1 \leq u_D \equiv c_2 - \sqrt{c_2^2 - c_1^2}$$

We also note that

$$\begin{aligned} u_1^2 + c_1^2 + 2u_1 c_2 &= \left[u_1 + \left(c_2 + \sqrt{c_2^2 - c_1^2} \right) \right] \left[u_1 + \left(c_2 - \sqrt{c_2^2 - c_1^2} \right) \right] \\ \rightarrow \quad f(u_1) &= (u_1^2 - u_R^2)(u_1^2 - u_D^2) \end{aligned}$$

$$\begin{aligned} \frac{u_2}{u_1} &= \frac{\rho_1}{\rho_2} = \frac{1}{2u_1^2} \left[(u_1^2 + c_1^2) \pm \sqrt{(u_1^2 - u_R^2)(u_1^2 - u_D^2)} \right] \\ \frac{\rho_2}{\rho_1} &= \frac{u_1}{u_2} = \frac{1}{2c_2^2} \left[(u_1^2 + c_1^2) \mp \sqrt{(u_1^2 - u_R^2)(u_1^2 - u_D^2)} \right] \end{aligned}$$

- The rapidly propagating ionization fronts, with $u_1 \geq u_R$ are called ***R-type fronts (R stands for “rarefied” or rapid)***. The dilatory ionization fronts are called ***D-type fronts (D stands for “dense” or dilatory)***.
 - ▶ An R-type front has $u_1 \geq u_R > c_2 > c_1$, and is supersonic with respect to the neutral medium.
 - ▶ A D-type front has $u_1 \leq u_D < c_1 < c_2$, and is subsonic with respect to the neutral medium.
- For a given front propagation speed u_1 , there are two possible values of the density ratio ρ_2/ρ_1 across the ionization front as a function of the propagation speed u_1 .
 - ▶ The front that has the ***larger density contrast*** is called a ***strong*** front.
 - ▶ The front that has the ***smaller density contrast*** is called a ***weak*** front.
 - ▶ Thus, there are four types of ionization front: weak R, strong R, weak D, strong D.

$$\frac{\rho_2}{\rho_1} = \frac{1}{2c_2^2} \left[(u_1^2 + c_1^2) \pm \sqrt{(u_1^2 - u_R^2)(u_1^2 - u_D^2)} \right]$$

R-front: $u_1 \geq u_R$ weak –; strong +
 D-front: $u_1 \leq u_D$ weak +; strong –

- ▶ The solutions for $u_1 = u_R$ and $u_1 = u_D$ are called “R-critical” and “D-critical”, respectively.

- Since c_2 exceeds c_1 by about one or two order of magnitude in an interstellar ionization front ($c_2 \gg c_1$),

$$u_R = c_2 + \sqrt{c_2^2 - c_1^2} \approx c_2 + c_2 \left(1 - \frac{1}{2} \frac{c_1^2}{c_2^2} - \frac{1}{8} \frac{c_1^4}{c_2^4} \right)$$

$$u_D = c_2 - \sqrt{c_2^2 - c_1^2} \approx c_2 - c_2 \left(1 - \frac{1}{2} \frac{c_1^2}{c_2^2} - \frac{1}{8} \frac{c_1^4}{c_2^4} \right)$$

$$u_R \approx 2c_2 \left(1 - \frac{1}{4} \frac{c_1^2}{c_2^2} \right) > c_2 > c_1 > u_D$$

$$u_D \approx \frac{1}{2} \frac{c_1^2}{c_2} \left(1 + \frac{1}{4} \frac{c_1^2}{c_2^2} \right) < c_1 < c_2 < u_R$$

- Approximate solutions:

R-critical $\frac{\rho_2}{\rho_1} \approx 2 \left(1 - \frac{1}{4} \frac{c_1^2}{c_2^2} \right)$ for $u_1 = u_R$

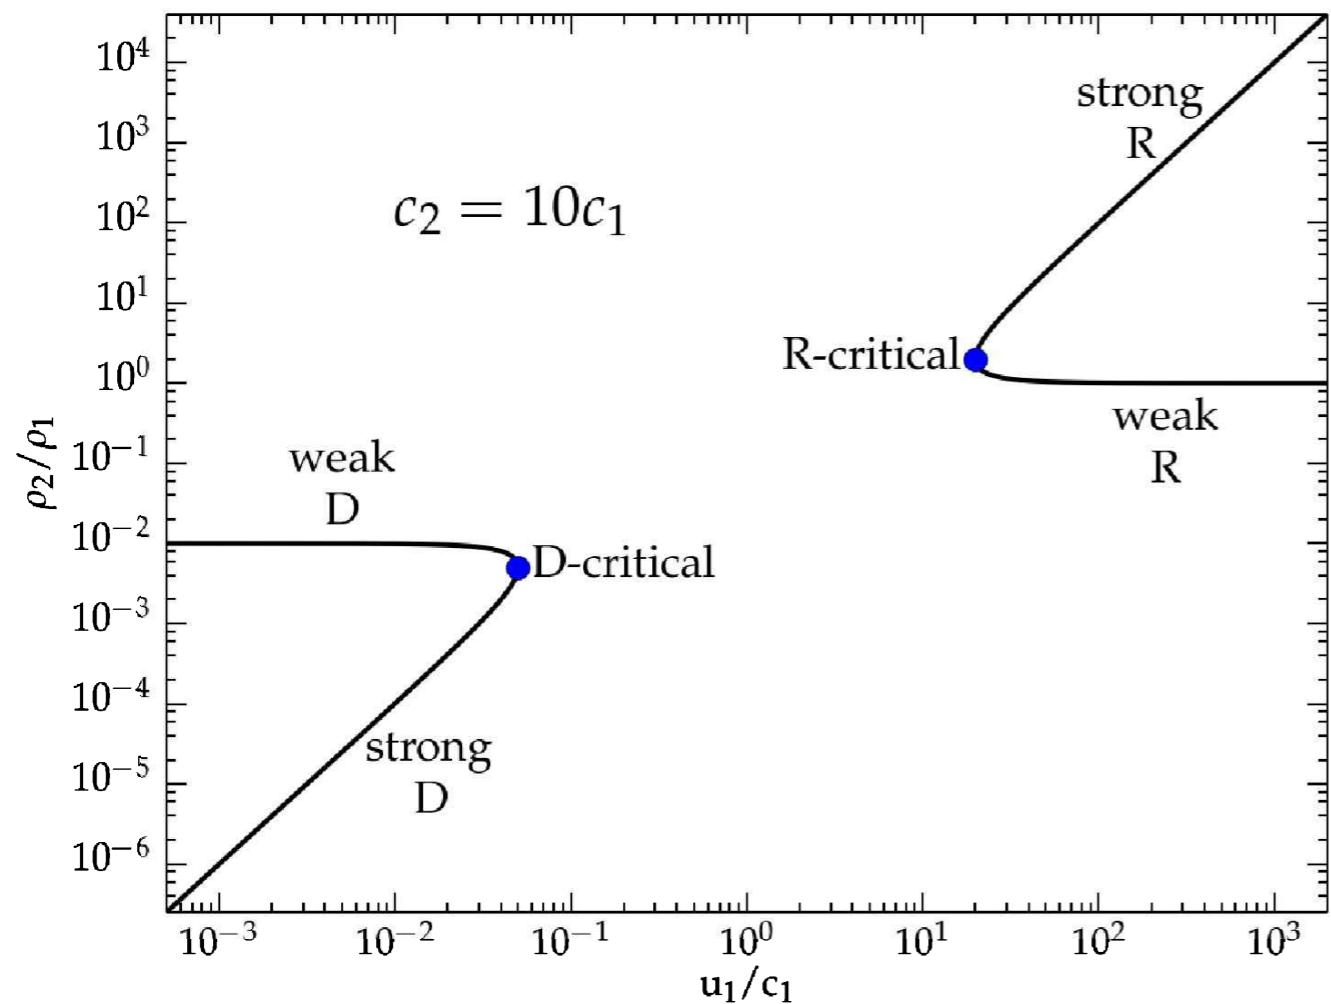

D-critical $\frac{\rho_2}{\rho_1} \approx \frac{1}{2} \frac{c_1^2}{c_2^2} \left(1 + \frac{1}{4} \frac{c_1^2}{c_2^2} \right)$ for $u_1 = u_D$

weak R-front $\frac{\rho_2}{\rho_1} \approx 1 + \frac{c_2^2}{u_1^2}$ for $u_1 \gg u_R$

strong R-front $\frac{\rho_2}{\rho_1} \approx \frac{u_1^2}{c_2^2} - 1$

weak D-front $\frac{\rho_2}{\rho_1} \approx \frac{c_1^2}{c_2^2} - \frac{u_1^2}{c_1^2}$ for $u_1 \ll u_D$

strong D-front $\frac{\rho_2}{\rho_1} \approx \frac{u_1^2}{c_1^2} \left(1 + \frac{c_2^2}{c_1^4} u_1^2 \right)$

	$u_R \approx 2c_2, \quad u_D \approx \frac{1}{2} \frac{c_1^2}{c_2}$
R-critical	$\frac{\rho_2}{\rho_1} \approx 2$ for $u_1 = u_R$
D-critical	$\frac{\rho_2}{\rho_1} \approx \frac{1}{2} \frac{c_1^2}{c_2^2}$ for $u_1 = u_D$
strong R-front	$\frac{\rho_2}{\rho_1} \approx \frac{u_1^2}{c_2^2}$ for $u_1 \gg u_R$
weak R-front	$\frac{\rho_2}{\rho_1} \approx 1$
weak D-front	$\frac{\rho_2}{\rho_1} \approx \frac{c_1^2}{c_2^2} \Rightarrow \rho_1 c_1^2 \approx \rho_2 c_2^2$ for $u_1 \ll u_D$
strong D-front	$\frac{\rho_2}{\rho_1} \approx \frac{u_1^2}{c_1^2}$

Figure 4.11 [Ryden]

- We note that the four types are not all relevant to H II regions.
 - ▶ For instance, the strong R type means a lower density in the upstream (neutral gas). The strong R-type fronts are in fact unstable (Rayleigh-Taylor instability). In H II regions, the neutral gas has a higher density than the ionized gas. (or the same density at the initial stage).
 - ▶ The strong D type implies that the density in neutral gas increases forever when the ionization front slows down.
- ***The fronts relevant to the HII regions are weak R-front and weak D-front.***

Evolution of Ionization Front

[1] Weak R front

We will assume that

$$c_1 = (kT_1/m_H)^{1/2}$$

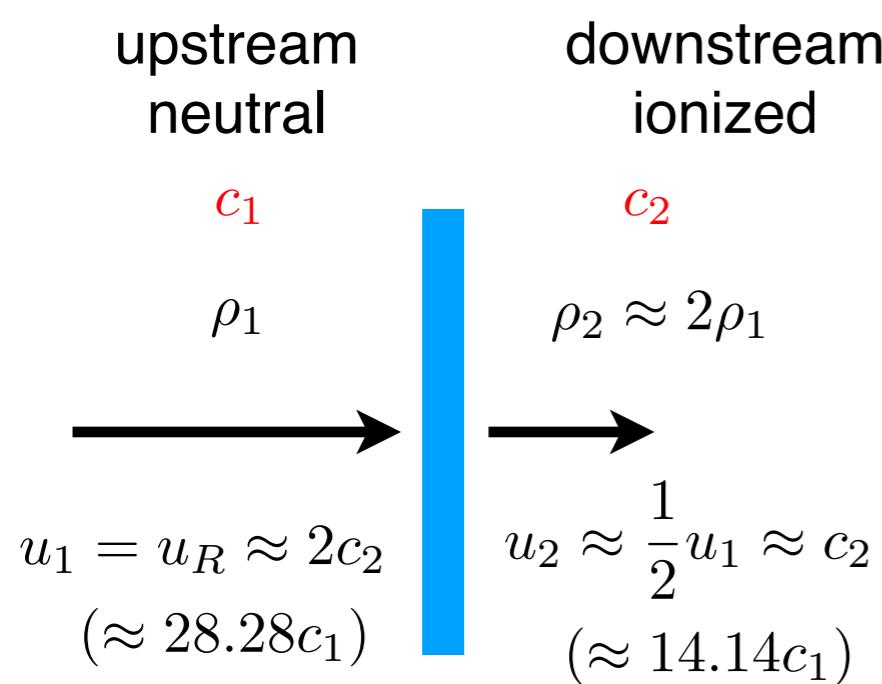

$$c_2 = (2kT_2/m_H)^{1/2} = (2T_2/T_1)^{1/2} c_1 = \sqrt{200} c_1$$

for $T_1 = 10^2 \text{ K}$, $T_2 = 10^4 \text{ K}$

(1) Weak R front:

- Initially, the photon flux J is very large. Thus, u_1 is very large, and the ionization front is initially a weak R-type front. The densities of neutral gas and ionized gas are nearly the same: $\rho_2/\rho_1 \approx 1$. (A weak R-type front compresses the gas only slightly.)
- As the ionization front expands, the flux of ionizing photons steadily decreases, and the propagation speed u_1 of the front slows down.

[2] R-critical front

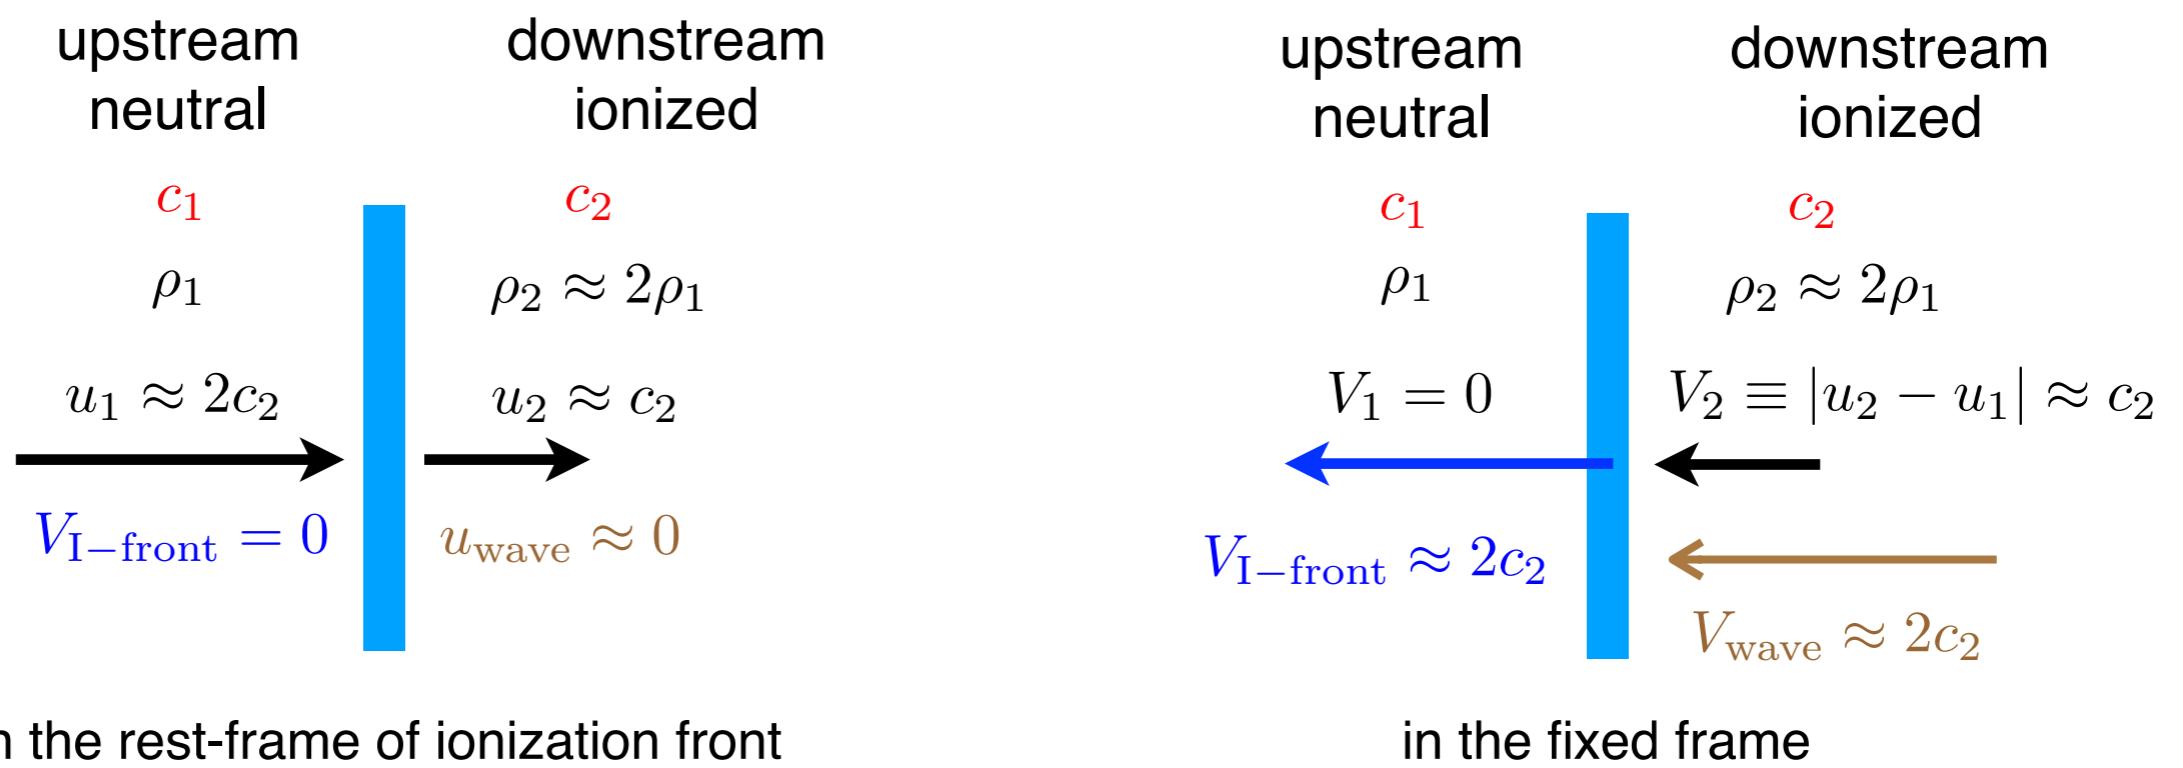

(2) R-critical front:

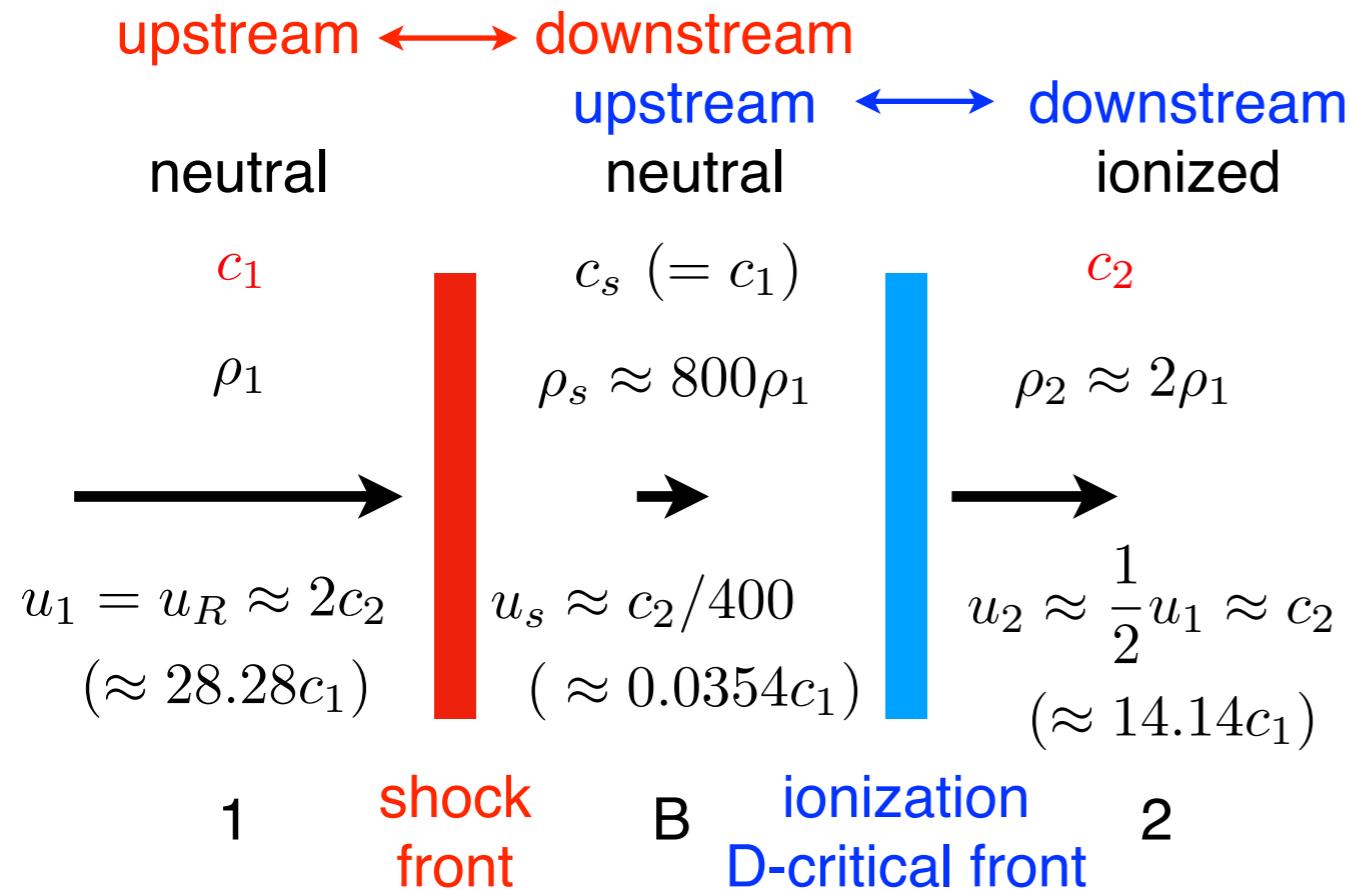

- Eventually, the speed drops to a value $u_1 = u_R \approx 2c_2$.
- At this point, the density ratio has risen to $\rho_2/\rho_1 \approx 2$.
- The speed of the ionized gas is $u_2 \approx (1/2)u_R \approx c_2$ relative to the ionization front, or $u_2 - u_1 \approx -c_2$ in a fixed frame of reference.
- As the ionization front slows down farther, the R-type front can no longer exist.

● How does the evolution proceed once the ionization front becomes R-critical?

- When the R-critical condition is reached, the gas in the H II region just behind the front is moving at a speed equal to $c_2 \gg c_1$.
- This should derive a shock wave into the pre-ionization front gas. Before this point, the large pressure discrepancy between the H II region and the H I region ahead of it has no chance to act dynamically, because the ionization front races ahead with speed u_1 so much faster than a pressure wave can catch it.
- When the ionization front slows down to a speed $u_1 = u_R \approx 2c_2$, however, the pressure wave (moving at a speed c_2 on top of the speed $u_2 \approx c_2$ that the H II fluid itself moves) can catch up with the ionization front and overtake it.
- In doing so, the pressure wave will steepen into a shock wave, thereby compressing the atomic gas behind it into a denser state that the lagging ionization front then has to eat into.

[3] D-critical front

(3) D-critical front:

- As the ionization front slows down farther, the R-type front can no longer exit. What happens next is that ***the R-critical ionization front splits into a pair of fronts (shock front + ionization front)***.
- ***A leading shock front is followed by a D-critical ionization front.*** The shock front is the boundary between two regions of gas with different density, pressure, and temperature, but no necessarily different ionization states. The shock front propagates with a supersonic speed relative to the gas in the upstream of the shock front.

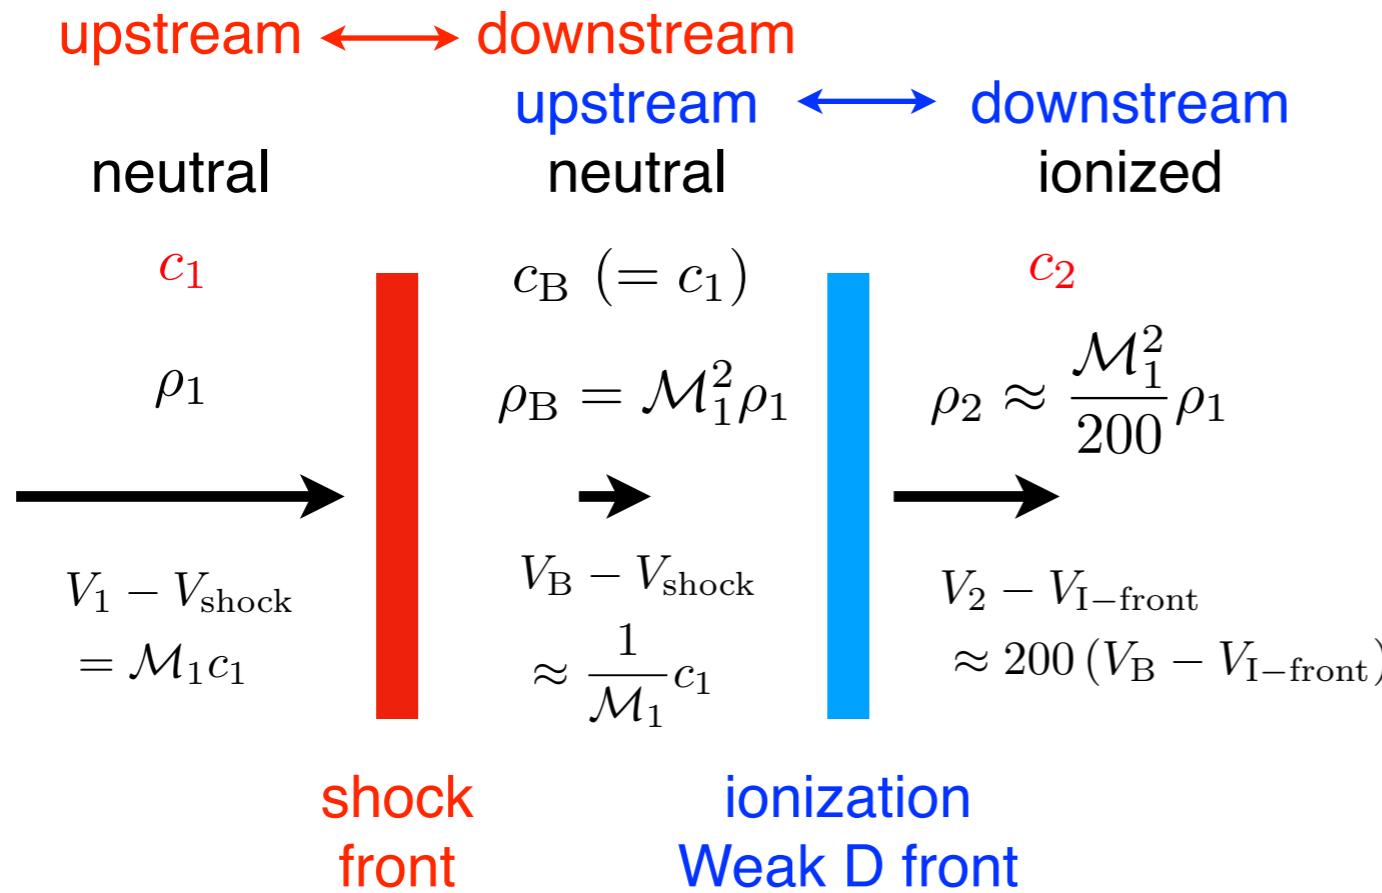

- We will assume ***an isothermal shock***. Then, the sound speed of the shocked region (B) must be $c_s = c_1$ (from the Rankin-Hugoniot jump condition). Then, using the condition for the D-critical, we obtain the density and speed of the shocked region (B):

$$\begin{aligned}\frac{\rho_2}{\rho_s} &\approx \frac{1}{2} \frac{c_1^2}{c_2^2} = \frac{1}{400} \\ \rho_s &\approx 400\rho_2 \approx 800\rho_1\end{aligned}\quad \begin{aligned}\frac{u_s}{u_2} &= \frac{\rho_2}{\rho_s} \\ u_s &\approx \frac{1}{400} u_2 \approx \frac{1}{400} c_2 \approx \frac{1}{\sqrt{800}} c_1 = 0.0354 c_1\end{aligned}$$

$$\longrightarrow \begin{aligned}\rho_s &\approx 800\rho_1 \\ u_s &\approx 0.0354 c_1 \\ (\mathcal{M}_1 &= \sqrt{800})\end{aligned}$$

- The shocked region (B) has a very high density, and is almost stationary relative to the ionization front. The velocities u_1, u_s, u_2 are measured in the rest-frame of I-front. The R-critical condition between 1 and 2 is still satisfied.

[4] Weak D front

(4) Weak D front:

- As the H II region expands still further, the leading shock front gradually weakens and the trailing D-critical front develops into a weak D-type front.
- Notice that the weakest of weak-D ionization fronts corresponds to the density discontinuity:

$$\frac{\rho_2}{\rho_B} = \frac{c_1^2}{c_2^2}$$

This is the condition for the static pressure equilibrium in isothermal gas,

$$\rho_2 c_2^2 = \rho_B c_1^2 \quad (P = \rho c_s^2)$$

the state that we expect for the final Strömgren sphere.

- The condition for the weak D-type front must be satisfied between the regions “B” and “2”.
- In addition to this condition, The shock jump condition should be satisfied between the regions “1” and “B”.
- However, notice that the velocities of the shock front and the ionization front can be different, in general.

$$V_{\text{shock}} \neq V_{\text{I-front}}$$

Intermediate States - expansion phase

- Assumptions:
 - The shocked gas layer is thin.
 - The ionization front follows the shock front and the expansion velocity of ionized sphere is approximately the same as the shock velocity.

$$V_{\text{I-front}} \approx V_{\text{shock}} \quad \frac{dR}{dt} = V_s$$

- Expansion:
 - The pressure behind a strong “isothermal” shock (high Mach number) is related to the shock velocity:

$$P_s = \rho_0 V_s^2 = n_0 m_H V_s^2$$

- Now assume that the pressure behind the shock wave is equal to the pressure of the ionized gas (pressure equilibrium).

$$P_i = 2n_i kT = n_i m_H c_i^2 \quad \left(c_i^2 \equiv \frac{2kT}{m_H} \right) \quad \text{for fully-ionized hydrogen gas}$$

- Then, the shock velocity is given by

$$P_s = P_i \rightarrow V_s^2 = \frac{n_i}{n_0} c_i^2 \rightarrow \frac{V_s^2}{c_i^2} = \frac{n_i}{n_0}$$

- We assume that the amount of fresh neutral gas to be ionized is very small. Then, the ionization balance for the region within R gives

$$Q_0 = \frac{4\pi}{3} R^3 n_i^2 \alpha_B \quad \rightarrow \quad R^3 = \frac{3Q_0}{4\pi n_i^2 \alpha_B} = R_s^3 \left(\frac{n_0}{n_i} \right)^2 \quad R_s = \text{Strömgren radius for the initial stage.}$$

- Combining with $\frac{V_s^2}{c_i^2} = \frac{n_i}{n_0}$, the equation for the expansion of the ionization front is

$$R^3 = R_s^3 \left(\frac{c_i}{V_s} \right)^4$$

$$\rho \equiv R/R_s, \quad \tau \equiv c_i t / R_s \quad \longrightarrow \quad \rho^3 \left(\frac{d\rho}{d\tau} \right)^4 = 1 \quad \rightarrow \quad \rho^{3/4} \frac{d\rho}{d\tau} = 1$$

- For a suitable boundary condition, we assume that the initial Strömgren sphere is set up at τ_0 (a very small fraction of the lifetime of the H II region):

$$R = R_s \text{ at } \tau = \tau_0$$

Then, the solution of the differential equation is

$$\rho = \left[1 + \frac{7}{4}(\tau - \tau_0) \right]^{4/7}$$

$$R = R_s \left(1 + \frac{7}{4} \frac{t - t_0}{R_s/c_i} \right)^{4/7}$$

-
- Expanding velocity is

$$\frac{dR}{dt} = c_i \left(1 + \frac{7}{4} \frac{t - t_0}{R_s/c_i} \right)^{-3/7}$$

- What is the time scale to reach the pressure equilibrium?

$$R(t_{\text{eq}}) = R_f \approx 34R_s$$

$$R_s \left(1 + \frac{7}{4} \frac{t_{\text{eq}}}{R_s/c_i} \right)^{4/7} \approx 34R_s$$

$$t_{\text{eq}} \approx 273 (R_s/c_i)$$

- The expanding velocity at this point is:

$$V_s = \frac{dR}{dt} = 0.71 c_i \quad \text{at} \quad t_{\text{eq}} = 273R_s/c_i$$

Timescales for typical HII region

- Let's examine the case of an O7V star with

$$Q_0 = 10^{49} \text{ s}^{-1}, \quad n_0 = 10^2 \text{ cm}^{-3}, \quad T = 10^4 \text{ K}$$

- Initial state: recombination time scale $t_{\text{rec}} = (n_0 \alpha_B)^{-1}$

$$R \approx R_s \text{ at } t = t_{\text{rec}}$$

$$R_s \approx 3 \text{ pc} (\approx 10^{19} \text{ cm})$$

$$t_{\text{rec}} \approx 1000 \text{ yr}$$

$$R(t) = R_s \left(1 - e^{-t/t_{\text{rec}}}\right)^{1/3}$$

$$\frac{dR}{dt} = \frac{R_s}{3t_{\text{rec}}} \frac{e^{-t/t_{\text{rec}}}}{(1 - e^{-t/t_{\text{rec}}})^{2/3}}$$

- Expansion phase: expansion timescale $t_{\text{exp}} = R_s/c_i$

expansion velocity : $V_s \leq 0.65 c_i$ at $t \geq t_{\text{exp}}$

$$c_i \approx 10 \text{ km s}^{-1}$$

$$t_{\text{exp}} \approx 3 \times 10^5 \text{ yr} \rightarrow t_{\text{exp}} \approx 200 t_{\text{rec}}$$

$$R = R_s \left(1 + \frac{7}{4} \frac{t - t_0}{R_s/c_i}\right)^{4/7}$$

$$\frac{dR}{dt} = c_i \left(1 + \frac{7}{4} \frac{t - t_0}{R_s/c_i}\right)^{-3/7}$$

- Final state: equilibrium timescale $t_{\text{eq}} \approx 273 R_s/c_i$ (from expansion phase model)

$$R = R_f \text{ at } t = t_{\text{eq}}$$

$$R_f/R_s \approx 34$$

$$t_{\text{eq}} \approx 10^8 \text{ yr} \rightarrow t_{\text{eq}} \approx 300 t_{\text{exp}}$$

Does the Stromgren sphere reach pressure equilibrium?

- Main-sequence lifetime of an ionizing star

$$t_{\text{MS}} \approx 10^{10} \left(\frac{M}{M_{\odot}} \right)^{-2} \text{ yr} \quad t_{\text{MS}} \approx 10^7 \text{ yr} \text{ for } M \approx 15M_{\odot}$$

- Size

- During the lifetime of an O star, which is less than 10 Myr, interstellar gas moving at 10 km/s will travel less than 100 pc, which is comparable with the diameter of the larger H II regions.
 - Thus, before an H II region has expanded very far, its central energy source will be extinguished.

- Time Scale:

- Main-sequence lifetime of an ionizing star is 10 times smaller than the time scale for the pressure equilibrium:

$$t_{\text{MS}} \approx 10^7 \text{ yr} \ll t_{\text{eq}} \approx 10^8 \text{ yr}$$

- It is unlikely that the final state (pressure equilibrium) of H II region can be reached during lifetime of star.

Hot Ionized Medium

 - Supernova Remnant
 - Local Hot Bubble

Introduction to Gas Dynamics

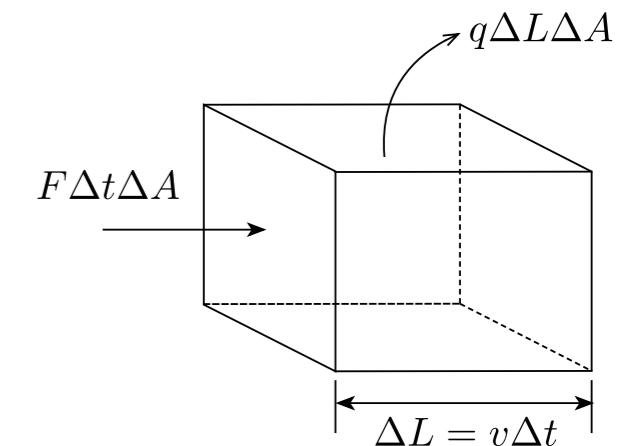

- Assumption for hydrodynamics:
 - particle mean free path << size of the region
 - We will describe the equations for conservation of mass, momentum and energy, in 1D space.

- ***Definition***

- Flux of a hydrodynamic quantity q :

Fluid moves a distance ΔL during a time interval Δt with a velocity v .

$$F\Delta t\Delta A = q\Delta L\Delta A \rightarrow F = qv$$

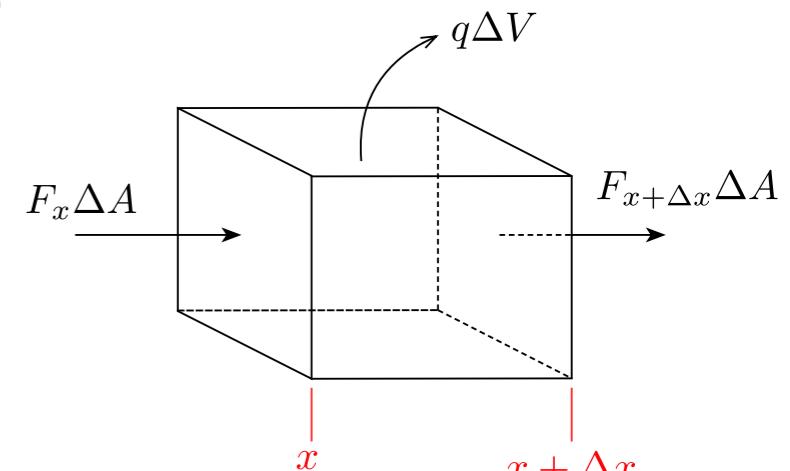

- ***Conservation equation for a quantity q***

- change of the quantity within a volume ΔV for a time interval Δt :

Here, Δt and Δx are independent.

$$\frac{q\Delta V|_{t+\Delta t} - q\Delta V|_t}{\Delta t} = F\Delta A|_x - F\Delta A|_{x+\Delta x}$$

$$\frac{\partial q}{\partial t} = -\frac{\partial F}{\partial x} \rightarrow \frac{\partial q}{\partial t} = -\frac{\partial(qv)}{\partial x}$$

- Here, no sources or sinks of the quantity within ΔV were assumed. If any, the loss and gain terms could be added in the right-hand side.

- ***Mass conservation (continuity equation)***

$$\frac{\partial \rho}{\partial t} = -\frac{\partial(\rho u)}{\partial x}$$

- ***Momentum conservation (Euler's equation)***

- ▶ (temporal) change of the momentum within a volume
= (spatial) change of momentum due to fluid flow + gas pressure acting on its surface

$$\frac{\partial}{\partial t}(\rho u) = -\frac{\partial}{\partial x} (\rho u^2 + P)$$

- ▶ Further terms could be added in the right-hand side, accounting for forces due to gravity, magnetic fields, radiation field, and viscosity.
- ▶ Viscous force is due to “internal friction” in the fluid (resistivity of the fluid to the flow), as two adjacent fluid parcels move relative to each other.)

viscous force $\propto \frac{\partial^2 u}{\partial x^2}$

The viscous force is usually much smaller than force due to gas pressure, but important in high-speed flows with large velocity gradients, as in accretion disks.

- ***Energy conservation***

- ▶ The first law of thermodynamics states that

heat added in a system = change in internal energy + work done on surroundings

$$dQ = dU + PdV$$

- ▶ Internal energy (per particle) for ideal gas is

$$U/N = \frac{3}{2}kT \text{ for monatomic gas (translation about 3 axes)}$$

$$U/N = \frac{5}{2}kT \text{ for diatomic gas (+rotation about 2 axes)}$$

$$U/N = 3kT \text{ for polyatomic gas (+rotation about 3 axes)}$$

Here, N is the number of particles.

An ideal gas is a theoretical gas composed of many randomly moving point particles whose only interactions are perfectly elastic collisions (no viscosity or heat conduction).

- ▶ In general, the internal energy per particle is

$$U/N = \frac{f}{2}kT \quad (f = \text{degree of freedom})$$

At high temperature, molecules have access to an increasing number of vibrational degrees of freedom, as they start to bend and stretch.

- The ideal gas law (the equation of state) for a perfect Maxwellian distribution.

$$PV = NkT$$

- **Specific heat capacity** is the amount of *heat energy required to raise the temperature of a material per unit of mass*.

- ▶ specific heat capacity at constant volume:

$$c_V \equiv \frac{1}{M} \left(\frac{\partial Q}{\partial T} \right)_V = \frac{1}{M} \left(\frac{\partial U}{\partial T} \right)_V \quad c_V = \frac{f}{2} \frac{k}{m}$$

M = total mass

$m = M/N$ = mass per particle

$m = \mu m_H$

(μ = mean atomic weight per particle)

- ▶ specific heat capacity at constant pressure:

$$c_P \equiv \frac{1}{M} \left(\frac{\partial Q}{\partial T} \right)_P = \frac{1}{M} \left(\frac{\partial U}{\partial T} \right)_P + \frac{P}{M} \left(\frac{\partial V}{\partial T} \right)_P = \frac{1}{M} \frac{f}{2} Nk + \frac{P}{M} \frac{Nk}{P} \quad \boxed{\downarrow}$$

$$\therefore c_P = \frac{f+2}{2} \frac{k}{m} = c_V + \frac{k}{m}$$

- ▶ Ratio of specific heat capacities:

$$\gamma \equiv \frac{c_P}{c_V} = \frac{f+2}{f} = \frac{5}{3} \text{ for monatomic gas}$$

$$= \frac{7}{5} \text{ for diatomic gas}$$

$$= \frac{4}{3} \text{ for polyatomic gas}$$

γ is called the adiabatic index.

$$c_P > c_V$$

This inequality implies that when pressure is held constant, some of the added heat goes into PdV work instead of into internal energy.

- Energy Conservation - limiting cases

► **Adiabatic flow** - negligible heat transport (Internal energy is changed only by work).

$$dQ = dU + PdV = Mc_VdT + PdV$$

$$dQ = 0$$

$$\rightarrow PdV = -Mc_VdT$$

$$PV = NkT$$

$$\rightarrow VdP + PdV = NkdT$$

We combine two equations and eliminate dT term:

$$\begin{aligned} VdP + PdV &= -\frac{Nk}{Mc_V} PdV \\ &= -\frac{k}{m c_V} PdV \end{aligned}$$

$$\begin{aligned} VdP &= -\left(1 + \frac{k}{m c_V}\right) PdV \\ &= -\frac{1}{c_V} \left(c_V + \frac{k}{m}\right) PdV \\ &= -\gamma PdV \end{aligned}$$

$$\frac{dP}{P} = -\gamma \frac{dV}{V}$$

We can rewrite this in terms of density:

$$\rho V = M$$

$$\rightarrow \rho dV + Vd\rho = 0$$

$$\rightarrow \frac{d\rho}{\rho} = -\frac{dV}{V}$$

$$\longrightarrow \frac{dP}{P} = \gamma \frac{d\rho}{\rho}$$

In summary,

$$\frac{dP}{P} = -\gamma \frac{dV}{V}$$

$$\frac{dP}{P} = \gamma \frac{d\rho}{\rho}$$

$$P \propto \rho^\gamma$$

$$P \propto V^{-\gamma}$$

$$\rightarrow T \propto V^{-(\gamma-1)}$$

adiabatic heating/cooling

-
- **Isothermal flow** - extremely efficient cooling (heat transport).

heat transport timescale << dynamic timescale

This implies the balance between heating and cooling, hence a constant temperature.

From the ideal gas law,

$$P = \frac{N}{V} kT = \rho \frac{kT}{m}$$

$$\begin{aligned} P &\propto \rho \\ P &\propto V^{-1} \end{aligned}$$

- In general, we have

$$\begin{aligned} P &\propto \rho^\gamma \\ P &\propto V^{-\gamma} \end{aligned}$$

($\gamma = 1$ for isothermal gas)

A gas that has an equation of state with this power-law form is called a ***polytope***, from the Greek polytropos, meaning “turning many ways” or “versatile.”

(A polystrope should not be confused with a polytrope, which is the n-dimensional generalization of a 2D polygon and 3D polyhedron.)

- **Specific internal energy** of the gas (per unit mass):

$$\begin{aligned}\epsilon &\equiv U/M \\ U/N &= \frac{f}{2}kT\end{aligned}\longrightarrow \epsilon = \frac{f}{2}\frac{kT}{m} \quad \text{or} \quad \epsilon = \frac{1}{\gamma-1}\frac{kT}{m} = \frac{1}{\gamma-1}\frac{P}{\rho}$$

- Total Energy (per unit volume):

► **Internal energy per unit volume:**

$$\mathcal{E}_{\text{int}} = \rho\epsilon = \frac{1}{\gamma-1}P$$

► **Kinetic energy due to bulk motion, per unit volume:**

$$\mathcal{E}_{\text{kin}} = \rho\frac{u^2}{2}$$

► **Work on unit volume:**

$$\mathcal{E}_{\text{mech}} = \frac{PdV}{dV} = P$$

$$\begin{aligned}\mathcal{E} &= \mathcal{E}_{\text{int}} + \mathcal{E}_{\text{kin}} + \mathcal{E}_{\text{mech}} \\ &= \rho\left(\frac{u^2}{2} + \epsilon\right) + P\end{aligned}$$

$$\longrightarrow \mathcal{E} = \rho\frac{u^2}{2} + \frac{\gamma}{\gamma-1}P$$

- **Energy conservation:**

$$\frac{\partial \mathcal{E}}{\partial t} = -\frac{\partial(u\mathcal{E})}{\partial x}$$

$$\frac{\partial}{\partial t} \left(\rho\frac{u^2}{2} + \frac{\gamma}{\gamma-1}P \right) = -\frac{\partial}{\partial x} \left[u \left(\rho\frac{u^2}{2} + \frac{\gamma}{\gamma-1}P \right) \right]$$

Sound Wave

- Suppose that we are surrounded by an ideal gas with a plane parallel symmetry:
 - We consider a region where the gas has initially a uniform density, pressure, and no bulk velocity: $\rho_0, P_0, u_0 = 0$

In the uniform gas, we introduce small perturbations of the form:

$$\begin{aligned} \rho(x, t) &= \rho_0 + \rho_1(x, t) & P_1 &= P - P_0 \\ u(x, t) &= u_1(x, t) & \propto (\rho_0 + \rho_1)^\gamma - \rho_0^\gamma \\ P(x, t) &= P_0 + P_1(x, t) & \propto \gamma \rho_0^{\gamma-1} \rho_1 & \longrightarrow P_1 = \frac{\gamma P_0}{\rho_0} \rho_1 \end{aligned}$$

We obtain:

$$\begin{array}{ccc} \frac{\partial \rho}{\partial t} = -\frac{\partial(\rho u)}{\partial x} & \rightarrow & \frac{\partial \rho_1}{\partial t} = -\rho_0 \frac{\partial u_1}{\partial x} \\ \rho \frac{\partial u}{\partial t} = -\rho u \frac{\partial u}{\partial x} - \frac{\partial P}{\partial x} & & \rho_0 \frac{\partial u_1}{\partial t} = -\frac{\partial P_1}{\partial x} = -\frac{\gamma P_0}{\rho_0} \frac{\partial \rho_1}{\partial x} \end{array} \quad \boxed{\frac{\partial^2 \rho_1}{\partial t^2} = -\frac{\gamma P_0}{\rho_0} \frac{\partial^2 \rho_1}{\partial x^2}}$$

- The resulting equation represents a sound wave (acoustic wave) with a constant sound speed:

$$c_s = \left(\frac{\gamma P}{\rho} \right)^{1/2} = \left(\frac{\gamma k T}{m} \right)^{1/2} \quad c_s \propto \rho^{(\gamma-1)/2}$$

For $\gamma > 1$, sound travels more rapidly in a denser gas.

-
- The sound speed is of the same order as the mean thermal velocity:

$$c_s = 1.2 \text{ km s}^{-1} \left(\frac{\gamma}{5/3} \right)^{1/2} \left(\frac{m}{m_p} \right)^{-1/2} \left(\frac{T}{100 \text{ K}} \right)^{1/2}$$

$(m_p = \text{proton mass})$

- **Sound crossing time:**

- ▶ sound crossing time = time it takes for a signal to cross a region of size L :

$$t_{\text{cross}} = L/c_s$$

- ▶ A small pressure gradient tends to be smoothed out within the sound crossing time. Generally, when a stationary gas is disturbed, the resultant changes in velocity, density, pressure, and temperature are communicated downstream at the sound speed.

Fast changes occurring on timescales $\ll t_{\text{cross}}$ will survive.

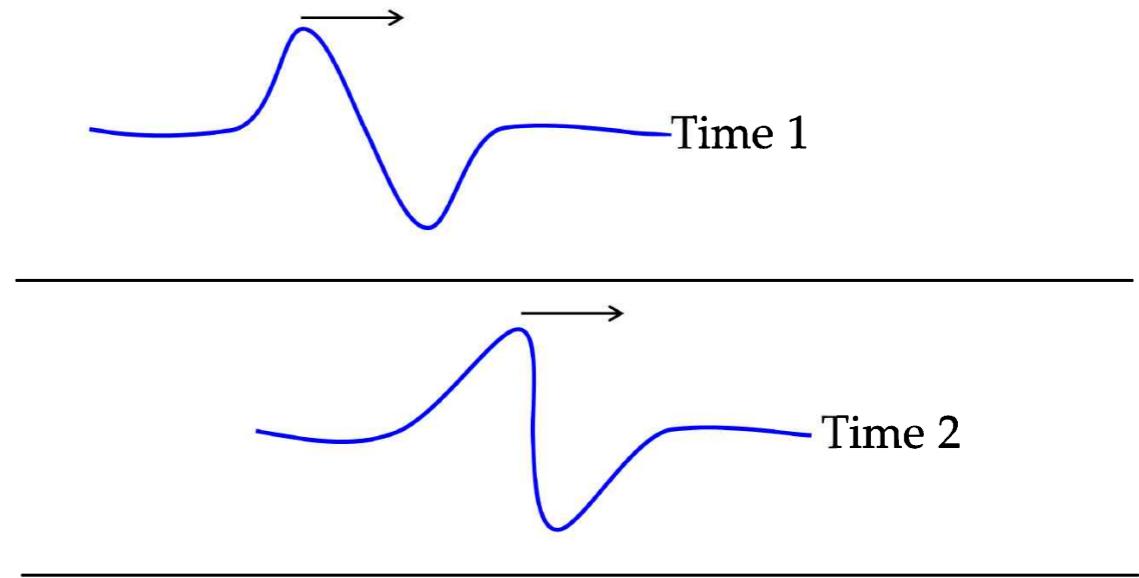

Slow changes occurring on timescales $\gg t_{\text{cross}}$ will be damped.

- **Mach number** = gas velocity / sound speed

$$\mathcal{M} \equiv u/c_s$$

Shock

- Shock
 - A low-amplitude sound wave traveling through a medium will be adiabatic; that is it will not increase the entropy of the gas through which it passes.
 - For an adiabatic process, the equation of state for the gas is
- $$c_s \propto \rho^{(\gamma-1)/2}$$
- Thus, for $\gamma > 1$, sound travels more rapidly in a denser gas.
 - ***For a supersonic gas, the motion itself is faster than the speed of communication, and instead of a smooth transition, the physical quantities (density, pressure, and temperature) undergo a sudden change in values over a small distance.*** This phenomenon is referred to as a shock.
 - We define the shock front as the region over which the velocity, density, and pressure of the gas undergo sudden changes. The shock front is a layer whose thickness is comparable to the mean free path between particle collisions.
 - The ordinary sound that we hear every day will not, in practice, steepen into shocks.
 - However, high amplitude pressure fluctuations will rapidly steepen into shocks.

Shock Front

- Jump condition (***Rankine-Hugoniot conditions***)

- Let

ρ = mass density, T = temperature,

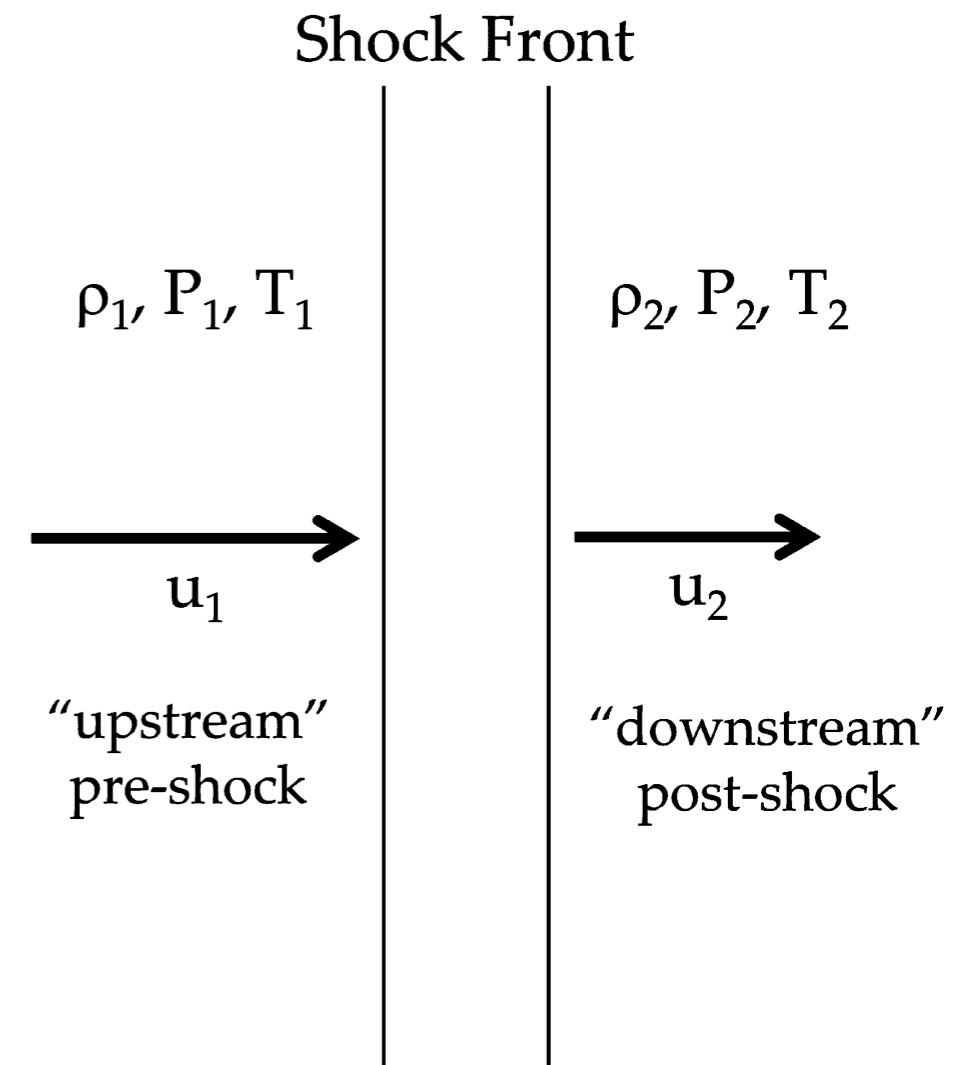

m = mean molecular mass

- If a patch is small compared to the shock front's radius of curvature, then we can treat the shock front as if it has ***plane parallel*** symmetry.

- ***It is convenient to use a frame of reference in which the shock front is stationary.***

- Let us consider a shock propagating with velocity V_s into a gas that is previously at rest. In the frame of reference of the shock, the gas in the pre-shock region is approaching at a velocity of $-V_s$.

- In this frame, the bulk velocity $u_1 = -V_s$ of the pre-shock (upstream) gas toward the shock front. The bulk velocity u_2 of the post-shock (downstream) gas points away from the shock front.

Plane parallel steady-state shock,
in the reference frame of the shock
front.

-
- Let's consider a steady state solution.
 - The gas properties immediately before being shocked (“1”) and immediately after being shocked (“2”) are obtained from the conservation laws:

$$\rho_1 u_1 = \rho_2 u_2$$

$$\rho_1 u_1^2 + P_1 = \rho_2 u_2^2 + P_2$$

$$u_1 \left(\rho_1 \frac{u_1^2}{2} + \frac{\gamma}{\gamma - 1} P_1 \right) = u_2 \left(\rho_2 \frac{u_2^2}{2} + \frac{\gamma}{\gamma - 1} P_2 \right)$$

Dividing the third equation with the first equation:

$$\frac{u_1^2}{2} + \frac{\gamma}{\gamma - 1} \frac{P_1}{\rho_1} = \frac{u_2^2}{2} + \frac{\gamma}{\gamma - 1} \frac{P_2}{\rho_2}$$

In summary,

$$\rho_1 u_1 = \rho_2 u_2$$

$$\rho_1 u_1^2 + P_1 = \rho_2 u_2^2 + P_2$$

$$\frac{u_1^2}{2} + \frac{\gamma}{\gamma - 1} \frac{P_1}{\rho_1} = \frac{u_2^2}{2} + \frac{\gamma}{\gamma - 1} \frac{P_2}{\rho_2}$$

Here, we assume that an adiabatic index is the same on both sides of the shock front.

- From the three equations, we should be able to derive the changes, ρ_2/ρ_1 , u_2/u_1 , and P_2/P_1 across the shock.

It is convenient to use a dimensionless number, the Mach number of the upstream:

$$\mathcal{M}_1 = u_1/c_1, \quad c_1^2 = \frac{\gamma P_1}{\rho_1} \quad \rightarrow \quad P_1 = \frac{u_1^2 \rho_1}{\gamma \mathcal{M}_1^2}$$

(1) To find the equation for densities:

$$\begin{aligned} \rho_1 u_1^2 + P_1 &= \rho_2 u_2^2 + P_2 \\ \rho_1 u_1 = \rho_2 u_2 \text{ and } P_1 = \frac{u_1^2 \rho_1}{\gamma \mathcal{M}_1^2} &\rightarrow \rho_1 u_1^2 + u_1^2 \frac{\rho_1}{\gamma \mathcal{M}_1^2} = \frac{(\rho_1 u_1)^2}{\rho_2} + P_2 \\ &\rightarrow P_2 = \rho_1 u_1^2 \left(1 + \frac{1}{\gamma \mathcal{M}_1^2} - \frac{\rho_1}{\rho_2} \right) \end{aligned}$$

Inserting these relations into the energy conservation equation:

$$\begin{aligned} \frac{u_1^2}{2} + \frac{\gamma}{\gamma-1} \frac{P_1}{\rho_1} &= \frac{u_2^2}{2} + \frac{\gamma}{\gamma-1} \frac{P_2}{\rho_2} \\ \rightarrow \frac{u_1^2}{2} + \frac{1}{\gamma-1} \frac{u_1^2}{\mathcal{M}_1^2} &= \frac{1}{2} \left(\frac{\rho_1 u_1}{\rho_2} \right)^2 + \frac{\gamma}{\gamma-1} \frac{\rho_1 u_1^2}{\rho_2} \left(1 + \frac{1}{\gamma \mathcal{M}_1^2} - \frac{\rho_1}{\rho_2} \right) \\ \rightarrow \frac{1}{2} + \frac{1}{\gamma-1} \frac{1}{\mathcal{M}_1^2} &= \frac{1}{2} \left(\frac{\rho_1}{\rho_2} \right)^2 + \frac{\gamma}{\gamma-1} \frac{\rho_1}{\rho_2} \left(1 + \frac{1}{\gamma \mathcal{M}_1^2} - \frac{\rho_1}{\rho_2} \right) \end{aligned}$$

$$ax^2 + bx - c = 0$$

where $x = \frac{\rho_1}{\rho_2}$

$$a = \frac{1}{2} - \frac{\gamma}{\gamma-1}$$

$$b = \frac{\gamma}{\gamma-1} + \frac{1}{(\gamma-1)\mathcal{M}_1^2}$$

$$c = \frac{1}{2} + \frac{1}{(\gamma-1)\mathcal{M}_1^2}$$

$$x = \frac{b^2 \pm \sqrt{b^2 + 4ac}}{2a}$$

$$\frac{\rho_1}{\rho_2} = \frac{-\left[\frac{\gamma}{\gamma-1} + \frac{1}{(\gamma-1)\mathcal{M}_0^2}\right] \pm \frac{\mathcal{M}_1^2 - 1}{\mathcal{M}_1^2(\gamma-1)}}{1 - \frac{2\gamma}{\gamma-1}}$$

→

$$\frac{\rho_1}{\rho_2} = 1 \quad \text{or} \quad \frac{(\gamma-1)\mathcal{M}_1^2 + 2}{(\gamma+1)\mathcal{M}_1^2}$$

$$\therefore \frac{\rho_2}{\rho_1} = \frac{(\gamma+1)\mathcal{M}_1^2}{(\gamma-1)\mathcal{M}_1^2 + 2}$$

(2) Now, we obtain the equation for pressures:

Divide the following equation

$$P_2 = \rho_1 u_1^2 \left(1 + \frac{1}{\gamma \mathcal{M}_1^2} - \frac{\rho_1}{\rho_2} \right)$$

with this

$$P_1 = \frac{u_1^2 \rho_1}{\gamma \mathcal{M}_1^2}$$

$$\frac{P_2}{P_1} = \gamma \mathcal{M}_1^2 \left(1 + \frac{1}{\gamma \mathcal{M}_1^2} - \frac{\rho_1}{\rho_2} \right)$$

$$= \gamma \mathcal{M}_1^2 \left(1 + \frac{1}{\gamma \mathcal{M}_1^2} - \frac{(\gamma-1)\mathcal{M}_1^2 + 2}{(\gamma+1)\mathcal{M}_1^2} \right)$$

$$\therefore \frac{P_2}{P_1} = \frac{2\gamma \mathcal{M}_1^2 - (\gamma-1)}{\gamma+1}$$

(3) Using the ideal gas law:

$$P = \frac{\rho k T}{m} \quad \rightarrow \quad \frac{T_2}{T_1} = \frac{\rho_1}{\rho_2} \frac{P_2}{P_1}$$

Using the equations for densities and pressures:

$$\therefore \frac{T_2}{T_1} = \frac{[(\gamma-1)\mathcal{M}_1^2 + 2][2\gamma \mathcal{M}_1^2 - (\gamma-1)]}{(\gamma+1)^2 \mathcal{M}_1^2}$$

In summary, we obtain the jump conditions:

$$\begin{aligned}\frac{\rho_2}{\rho_1} &= \frac{(\gamma + 1)\mathcal{M}_1^2}{(\gamma - 1)\mathcal{M}_1^2 + 2} = \frac{u_1}{u_2} \\ \frac{P_2}{P_1} &= \frac{2\gamma\mathcal{M}_1^2 - (\gamma - 1)}{\gamma + 1} \\ \frac{T_2}{T_1} &= \frac{[(\gamma - 1)\mathcal{M}_1^2 + 2][2\gamma\mathcal{M}_1^2 - (\gamma - 1)]}{(\gamma + 1)^2\mathcal{M}_1^2}\end{aligned}$$

In the lab frame, let V_s = shock velocity, v_1, v_2 = gas velocities in upstream (pre-shock) and downstream (post-shock), respectively ($v_1 = 0$) .

Using $u_1 = -V_s$ and $u_2 = v_2 - V_s$, we have

$$\frac{-V_s}{v_2 - V_s} = \frac{(\gamma + 1)\mathcal{M}_1^2}{(\gamma - 1)\mathcal{M}_1^2 + 2}$$

$$v_2 = \frac{2(\mathcal{M}_1^2 - 1)}{(\gamma + 1)\mathcal{M}_1^2} V_s$$

Note a typo in Equation (16.12) of Kwok's book.

$$\frac{\rho_2}{\rho_1} = \frac{(\gamma + 1)\mathcal{M}_1^2}{(\gamma - 1)\mathcal{M}_1^2 + 2} = \frac{u_1}{u_2}$$

$$\frac{P_2}{P_1} = \frac{2\gamma\mathcal{M}_1^2 - (\gamma - 1)}{\gamma + 1}$$

$$\frac{T_2}{T_1} = \frac{[(\gamma - 1)\mathcal{M}_1^2 + 2][2\gamma\mathcal{M}_1^2 - (\gamma - 1)]}{(\gamma + 1)^2\mathcal{M}_1^2}$$

For a strong shock: $\mathcal{M}_1 \gg 1$

$$P_2 \approx \frac{2\gamma\mathcal{M}_1^2}{\gamma + 1} P_1 \xrightarrow{P_1 = c_1^2 \frac{\rho_1}{\gamma}} \frac{2\gamma(u_1/c_1)^2}{\gamma + 1} c_1^2 \frac{\rho_1}{\gamma}$$

$$T_2 \approx \frac{2(\gamma - 1)\gamma}{(\gamma + 1)^2} \mathcal{M}_1^2 T_1 = \frac{2(\gamma - 1)\gamma}{(\gamma + 1)^2} \left(\frac{u_1}{c_1}\right)^2 T_1$$

speed of the downstream in the laboratory frame:

$$\frac{\rho_2}{\rho_1} \simeq \frac{\gamma + 1}{\gamma - 1}$$

$$\frac{u_2}{u_1} \simeq \frac{\gamma - 1}{\gamma + 1}$$

$$P_2 \simeq \frac{2}{\gamma + 1} \rho_1 u_1^2$$

$$T_2 \simeq \frac{2(\gamma - 1)}{(\gamma + 1)^2} \frac{m}{k} u_1^2$$

$$v_2 \simeq \frac{2}{(\gamma + 1)} V_s$$

monatomic gas: $\gamma = 5/3$

$$\frac{\rho_2}{\rho_1} \simeq 4$$

$$\frac{u_2}{u_1} \simeq \frac{1}{4}$$

$$P_2 \simeq \frac{3}{4} \rho_1 u_1^2$$

$$T_2 \simeq \frac{3}{16} \frac{m}{k} u_1^2$$

$$v_2 \simeq \frac{3}{4} V_s$$

For an isothermal shock: $\gamma = 1$

speed of the downstream in the laboratory frame:

$$\frac{\rho_2}{\rho_1} = \mathcal{M}_1^2 = \frac{u_1}{u_2}$$

$$P_2 = \mathcal{M}_1^2 P_1 = \rho_1 u_1^2$$

$$T_2 = T_1$$

$$v_2 = \left(1 - \frac{1}{\mathcal{M}_1^2}\right) V_s$$

$$u_1 u_2 = c_1^2$$

$$c_2 = c_1$$

- Consider a strong shock
 - ***No matter how strong the shock is, the gas can only be compressed by a factor of at most 4:***

$$\begin{aligned} \frac{\rho_2}{\rho_1} &\approx 4 & \text{for } \gamma = 5/3 \\ P_2 &\approx \frac{3}{4} \rho_1 u_1^2 & (\text{monatomic gas}) \\ T_2 &\approx \frac{3}{16} \frac{m}{k} u_1^2 \end{aligned}$$

Note that

$$m = \frac{1.4m_{\text{H}}}{1.1} = 1.273m_{\text{H}} \quad \text{for neutral gas}$$

$$m = \frac{1.4m_{\text{H}}}{2.3} = 0.609m_{\text{H}} \quad \text{for ionized gas}$$

$n \simeq 2.3n_{\text{H}}$ for ionized gas,
 one electron from an ionized hydrogen
 two electrons from a doubly-ionized helium.

- In the lab frame, V_s = shock velocity, v_1, v_2 = gas velocities in upstream and downstream, respectively.

$$u_1 = v_1 - V_s = -V_s \quad (v_1 = 0)$$

$$u_2 = v_2 - V_s$$

- Then, the post-shock velocity is

$$\frac{u_2}{u_1} = \frac{v_s - V_s}{-V_s} = \frac{1}{4} \quad \Rightarrow \quad v_2 = \frac{3}{4} V_s$$

- Hence, the post-shock moves in the same direction as the shock front with a velocity of $3/4$ of the shock velocity.

- Then, the post-shock pressure, temperature, specific internal energy, and specific kinetic energy are, respectively,

$$P_2 = \frac{3}{4} \rho_1 V_s^2$$

$$T_2 = \frac{3m}{16k} V_s^2$$

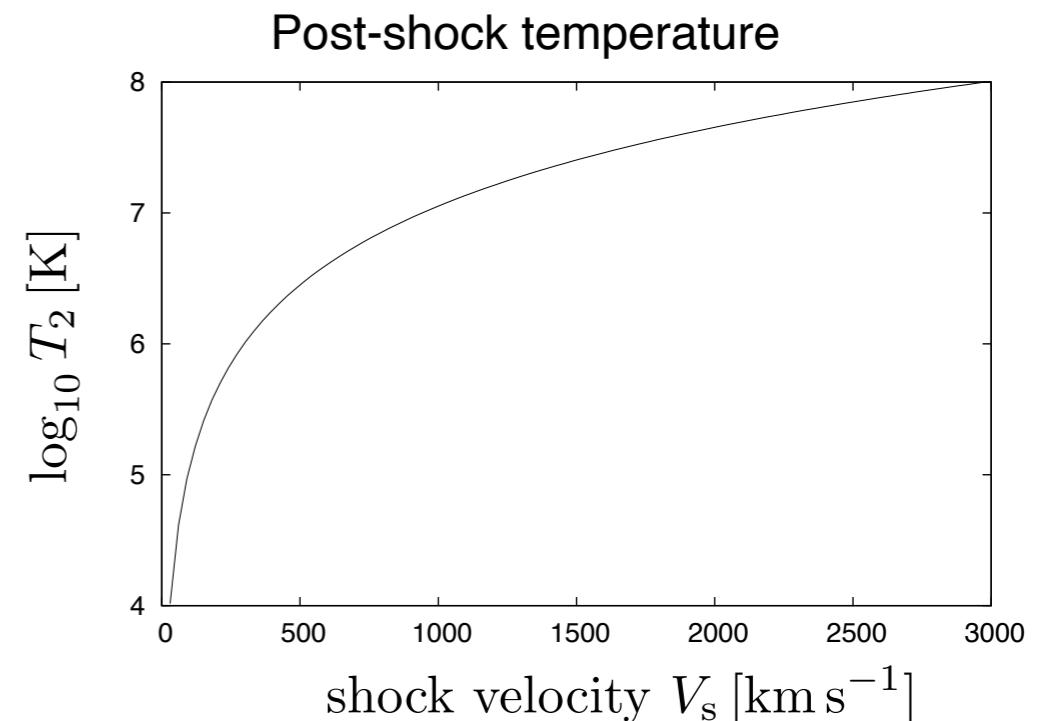

for $\gamma = 5/3$

$$\frac{\mathcal{E}_{\text{int},2}}{\rho_2} = \epsilon_2 = \frac{3 P_2}{2 \rho_2} = \frac{3}{2} \frac{(3/4) \rho_1 V_s^2}{4 \rho_1}$$

$$\frac{\mathcal{E}_{\text{kin},2}}{\rho_2} = \frac{1}{2} v_2^2$$

$$\frac{\mathcal{E}_{\text{int},2}}{\rho_2} = \frac{9}{32} V_s^2$$

$$\frac{\mathcal{E}_{\text{kin},2}}{\rho_2} = \frac{9}{32} V_s^2$$

- A strong shock can produce very high pressures and temperatures. An interstellar shock front with propagation speed $V_s \sim 1000 \text{ km s}^{-1}$ (typical for a supernova shock wave) produces shock heated gas with

$$T_2 \approx 1.38 \times 10^7 \text{ K} \left(\frac{m}{0.609 m_H} \right) \left(\frac{V_s}{1000 \text{ km s}^{-1}} \right)^2$$

or $T_2 \approx 1.38 \times 10^5 \text{ K} \left(\frac{m}{0.609 m_H} \right) \left(\frac{V_s}{100 \text{ km s}^{-1}} \right)^2$

assuming the shocks gas is fully ionized hydrogen.

- In general, shock fronts convert supersonic gas into subsonic gas in the shock's frame of reference. Shocks increase density, pressure, and temperature, and decrease bulk velocity relative to the shock front. Shocks act as entropy generators.

General Properties of the HIM

- Hot Ionized Medium, coronal gas
 - About half the volume of the ISM in our Galaxy is occupied by the HIM.
 - Temperature $\sim 10^6$ K.
 - Typical ion number density $n \sim 0.004 \text{ cm}^{-3}$
 - It provides only $\sim 0.2\%$ of the mass of the ISM, despite being the largest contributor to its volume.
 - The HIM is hot because it has been heated by shock fronts that result from supernova explosions.
 - ***We live in the “Local Bubble”, which is $\sim 100 \text{ pc}$ in size. The Local Bubble is thought to have been blown by a supernova that went off $\sim 10 \text{ Myr}$ ago.***

Collisional Ionization Equilibrium

- CIE
 - CIE assumes that the plasma is in a steady state, and that collisional ionization, charge exchange, radiative recombination, and dielectronic recombination are the only processes altering the ionization balance.
 - ▶ Note that the reverse process to collisional ionization is a three-body recombination, which is unlikely to occur.
 - The ionization fractions for each element depend only on the gas temperature, with no dependence on the gas density.
- Ionization fraction
 - For hydrogen, the balance equation is : ionization rate = recombination rate

$$n_e n(\text{H}^0) k_{\text{ci}, \text{H}} = n_e n(\text{H}^+) \alpha_{\text{A}, \text{H}} \quad n(\text{H}^0) + n(\text{H}^+) = n(\text{H})$$

- The rate coefficients for collisional ionization and radiative recombination are:

$$k_{\text{ci}, \text{H}} = 5.849 \times 10^{-9} T_4^{1/2} e^{-15.782/T_4} [\text{cm}^3 \text{s}^{-1}]$$

$$\begin{aligned} \alpha_{\text{A}, \text{H}} &= 4.13 \times 10^{-13} T_4^{-0.7131 - 0.0115 \ln T_4} [\text{cm}^3 \text{s}^{-1}] \quad \text{for } 30 \text{ K} < T < 3 \times 10^4 \text{ K} \\ &= 5 \times 10^{-16} T_7^{-1.5} \quad \text{for } T > 10^6 \text{ K} \end{aligned} \quad [\text{from Draine}]$$

$$\alpha_{\text{A}, \text{H}} = 1.269 \times 10^{-13} [\text{cm}^3 \text{s}^{-1}] \frac{x^{1.503}}{(1 + (x/0.522)^{0.47})^{1.923}} \quad \text{where } x = 2 \times 157807 \text{ K}/T \quad [\text{Hui \& Gendin 1997, MNRAS}]$$

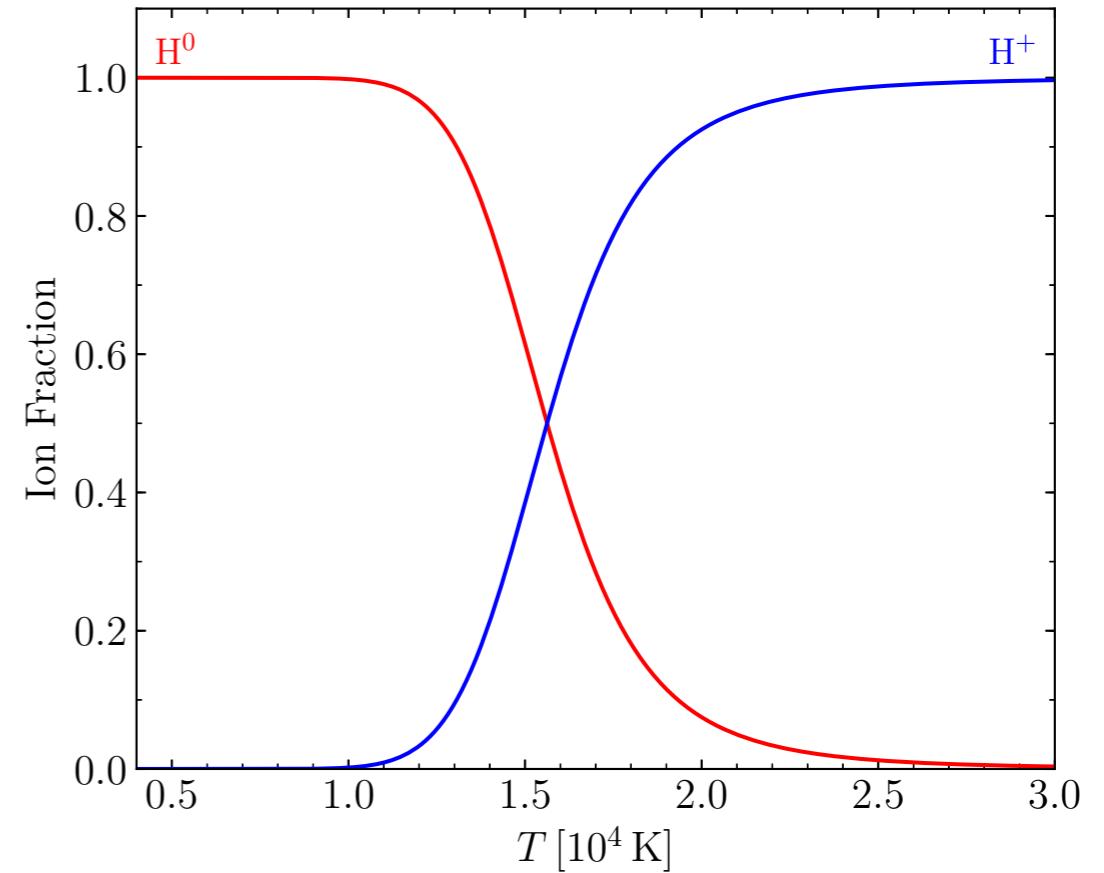

- The ionization fraction is

$$\begin{aligned}x &\equiv \frac{n(\text{H}^+)}{n(\text{H}^0) + n(\text{H}^+)} \\&= \frac{k_{\text{ci},\text{H}}}{k_{\text{ci},\text{H}} + \alpha_{\text{A},\text{H}}}\end{aligned}$$

- The ion fractions are

$$x \approx 0.002 \text{ at } T = 10^4 \text{ K}$$

$$1 - x \approx 3 \times 10^{-7} \text{ at } T = 10^6 \text{ K}$$

H II regions with $T = 10^4$ K are photoionized by UV photons from hot stars.

Hydrogen gas with $T = 10^6$ K is almost entirely collisionally ionized.

- For Helium, the balance equations are:

$$n(\text{He}^+) \alpha_{10} = n(\text{He}^0) k_{01}$$

$$n(\text{He}^+) k_{12} = n(\text{He}^{2+}) \alpha_{21}$$

$$n(\text{He}) = n(\text{He}^0) + n(\text{He}^+) + n(\text{He}^{2+})$$

Here, ij indicates $X^{i+} \rightarrow X^{j+}$.

- The rate coefficients are

$$k_{01} = 2.39 \times 10^{-11} T^{1/2} e^{-285,335/T}$$

from Cen (1992, ApJS)

$$k_{12} = 5.68 \times 10^{-12} T^{1/2} e^{-631,515/T}$$

$$\alpha_{10} = 1.50 \times 10^{-10} T^{-0.6353} \text{ radiative recombination}$$

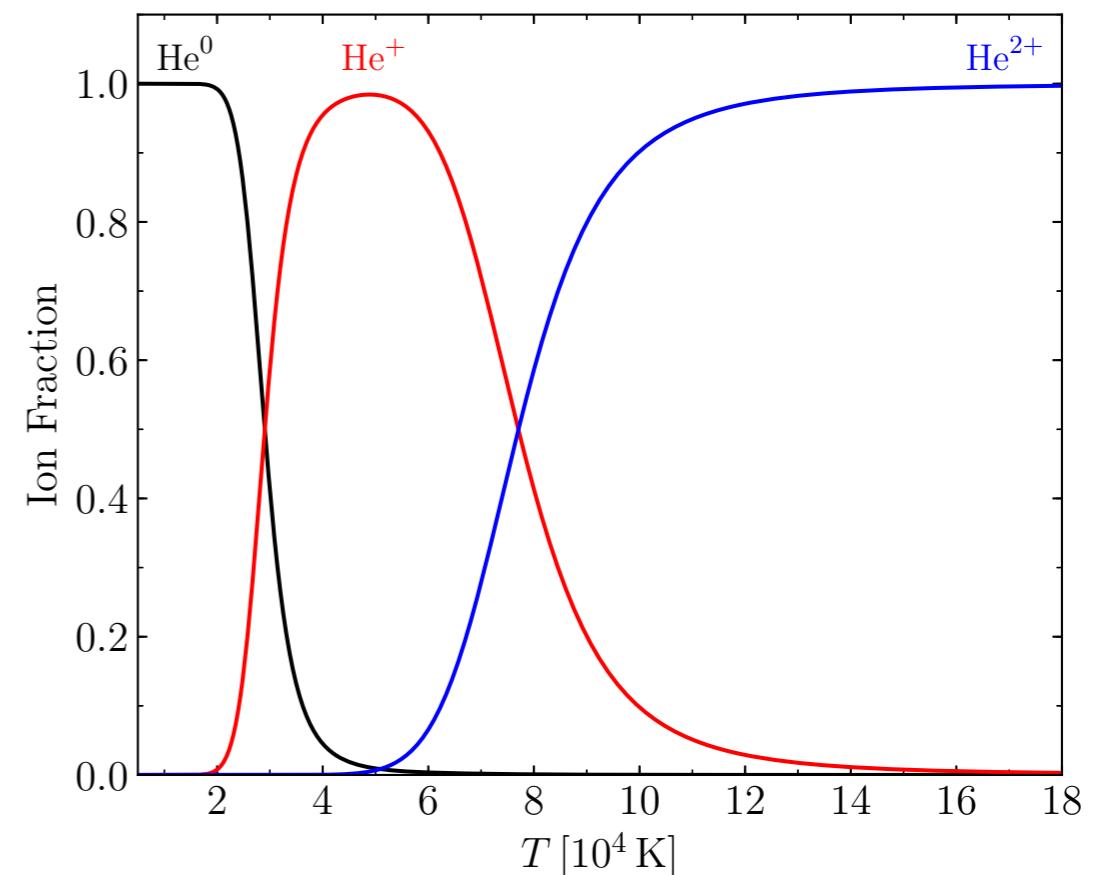

$$+ 1.9 \times 10^{-3} T^{-1.5} e^{-470,000/T} (1 + 0.3e^{-94,000/T}) \text{ dielectronic recombination (but not significant)}$$

$$\alpha_{21} = 3.36 \times 10^{-10} T^{-1/2} T_3^{-0.2} / (1 + T_6^{0.7})$$

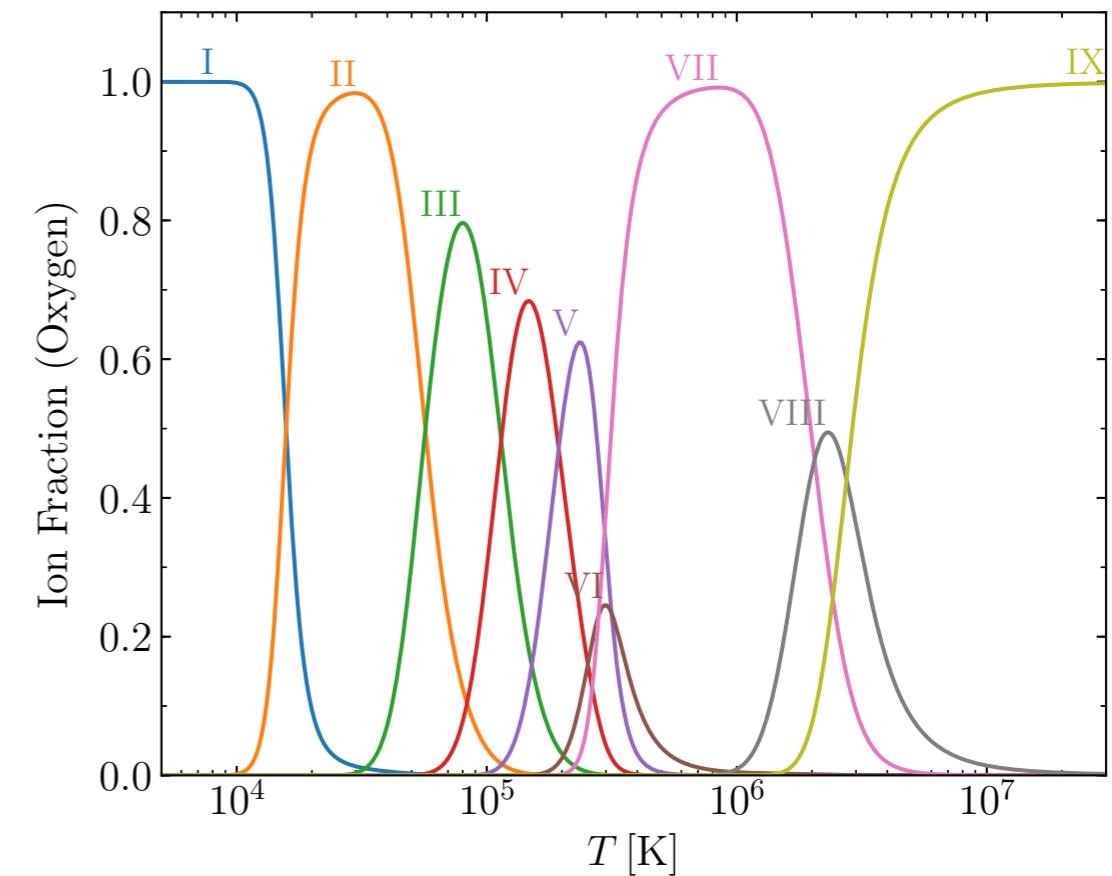

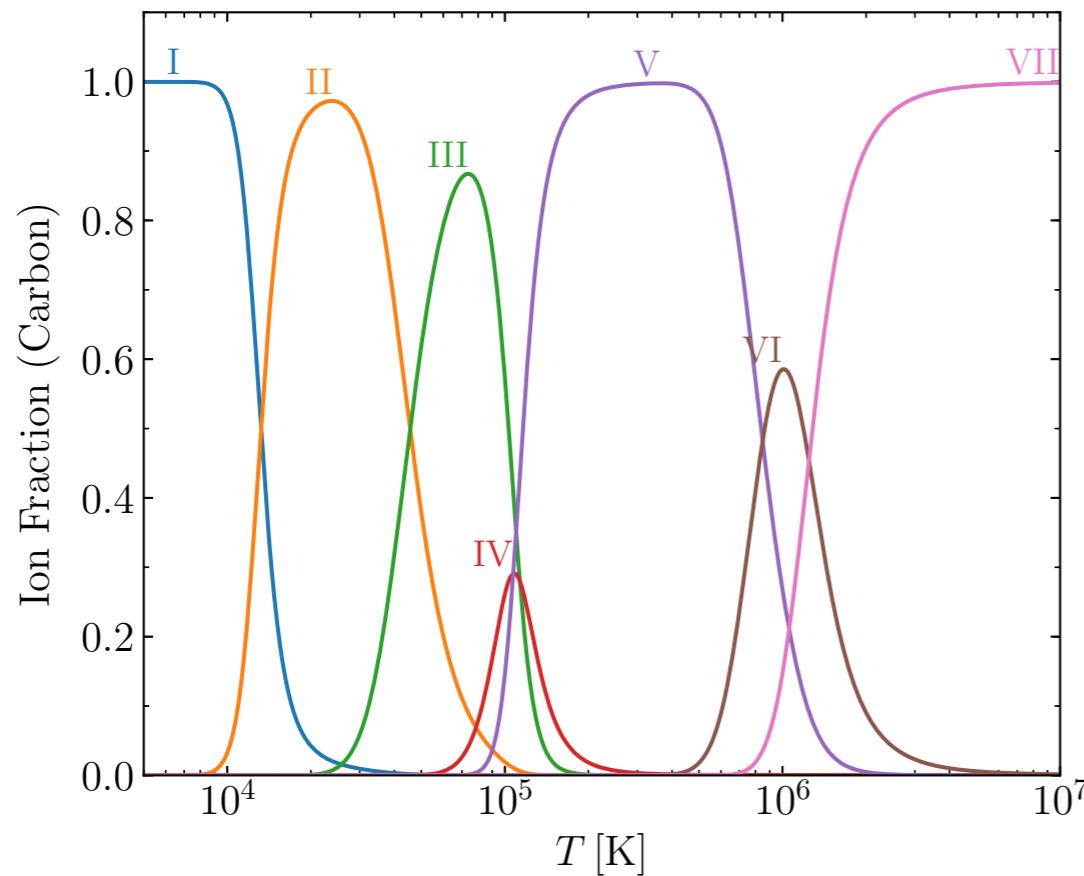

- Using the above rate coefficients, the ionization fractions can be estimated as follows:

$$x \equiv \frac{n(\text{He}^+)}{n(\text{He})} = \frac{1}{1 + \alpha_{10}/k_{01} + k_{12}/\alpha_{21}}$$

$$y \equiv \frac{n(\text{He}^{2+})}{n(\text{He})} = \frac{k_{12}}{\alpha_{21}} x$$

- Heavy Elements
 - ▶ The calculation is usually done numerically, for instance, using CHIANTI
[CHIANTI: https://www.chiantidatabase.org/](https://www.chiantidatabase.org/)
 - ▶ For instance, the ion fractions of Carbon and Oxygen as a function of temperature are:

- At $T \sim 10^6$ K, we expect a mix of C V, C VI, and C VII.
- At $T \sim 4 \times 10^6$ K and higher, almost all the carbon will be in the form of fully ionized C VII.

The figures were calculated using CHIANTI.

Cooling in CIE

- ***Cooling function***

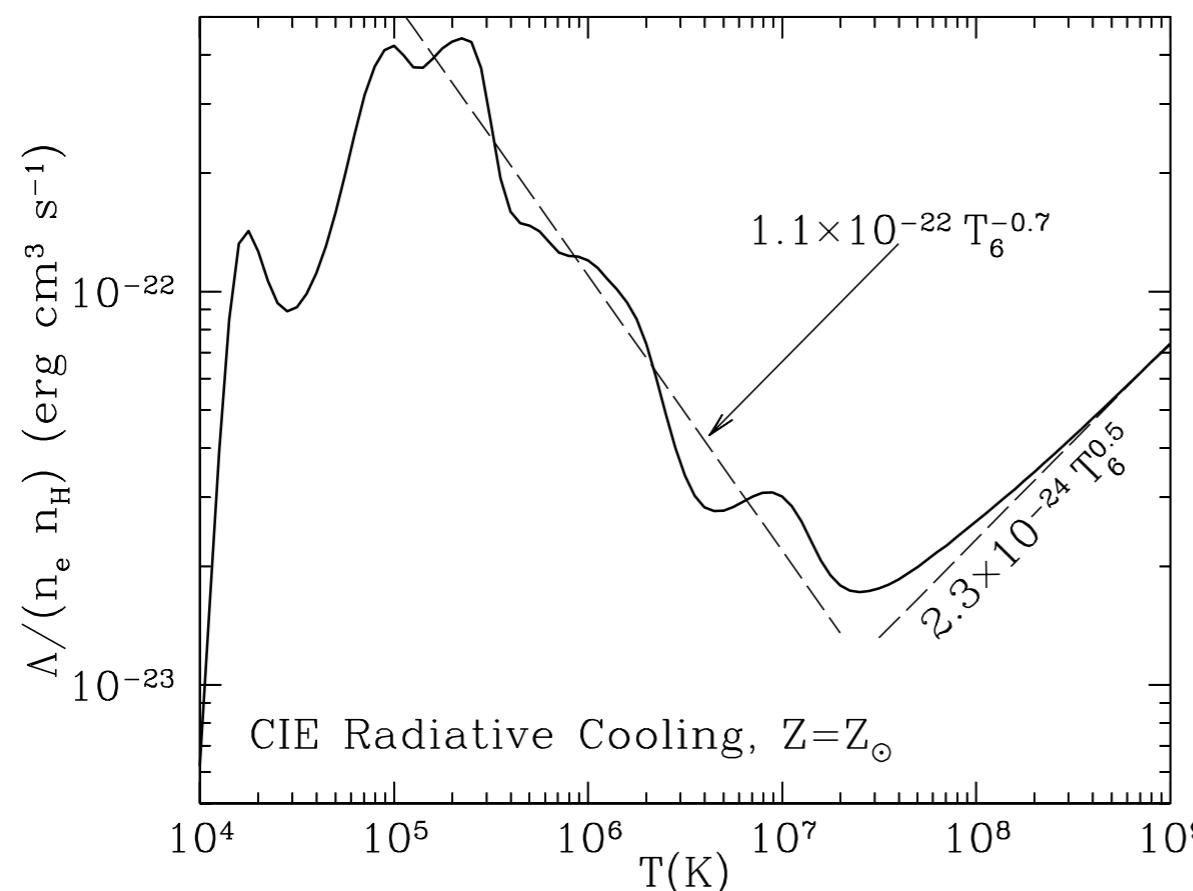

- At temperature $T > 10^4$ K, ionization of hydrogen provides enough free electrons so that collisional excitation of atoms or ions is dominated by electron collisions.
- At low densities, every collisional excitation is followed by a radiative decay, and the rate of removal of thermal energy per unit volume can be written:

$$\Lambda = n_e n_H f_{\text{cool}}(T)$$

The ***radiative cooling function*** $f_{\text{cool}}(T) \equiv \Lambda / (n_H n_e)$ is a function of ***temperature*** and of the ***elemental abundances*** relative to hydrogen.

- At high densities, radiative cooling can be suppressed by collisional deexcitation, and the cooling function will then depend on density, in addition to T and elemental abundances.
- If ionizing radiation is present, the ionization balance may depart from CIE, and the radiative cooling function will also depend on the spectrum and intensity of the ionizing radiation.

Fig 34.1
Draine

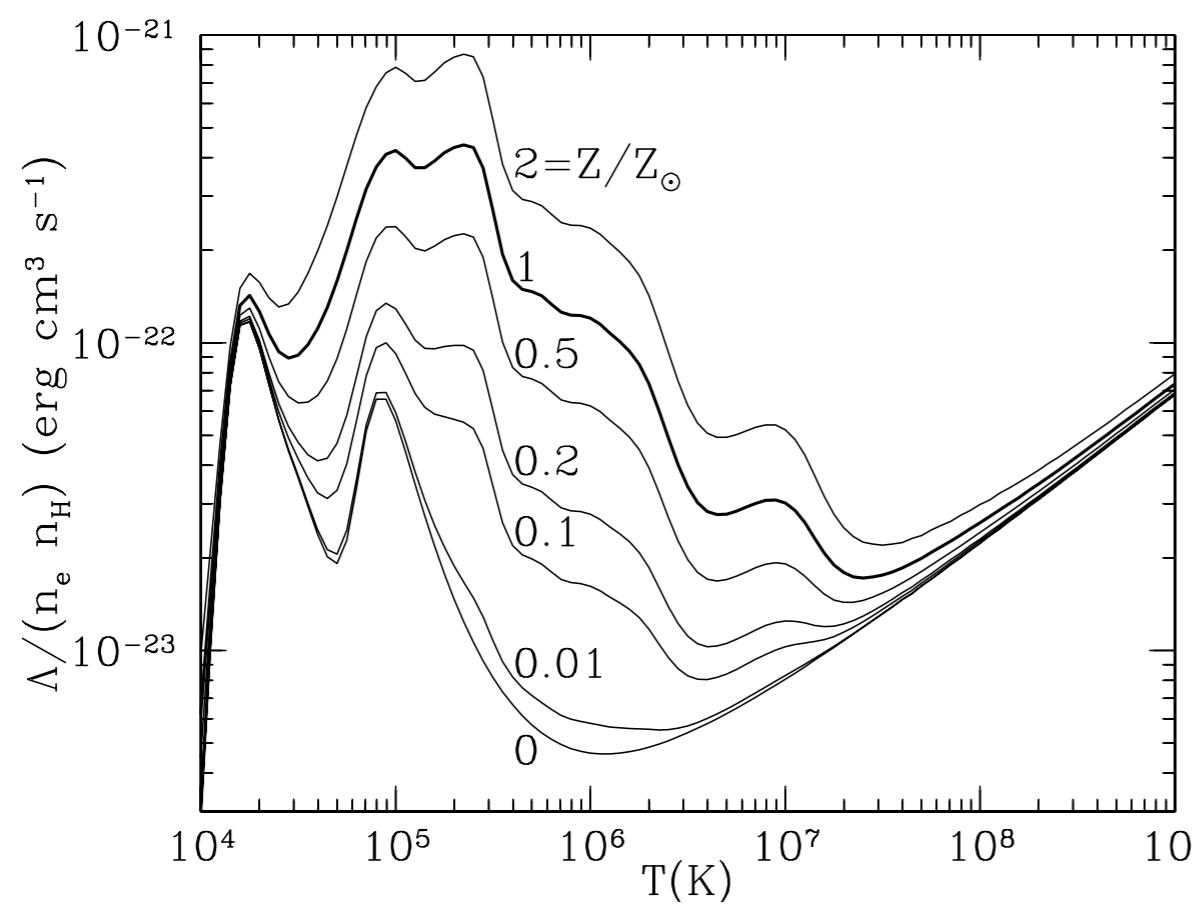

Radiative Cooling Function for solar-abundance

- At $T < 10^7$ K, the cooling is dominated by collisional excitation of bound electrons.
- At high temperatures, the ions are fully stripped of electrons, and bremsstrahlung (free-free) cooling dominates.

$$\Lambda/n_e n_H \approx 1.1 \times 10^{-22} T_6^{-0.7} [\text{erg cm}^3 \text{s}^{-1}]$$

$$(10^5 < T < 10^{7.3} \text{ K})$$

Fig 34.2
Draine

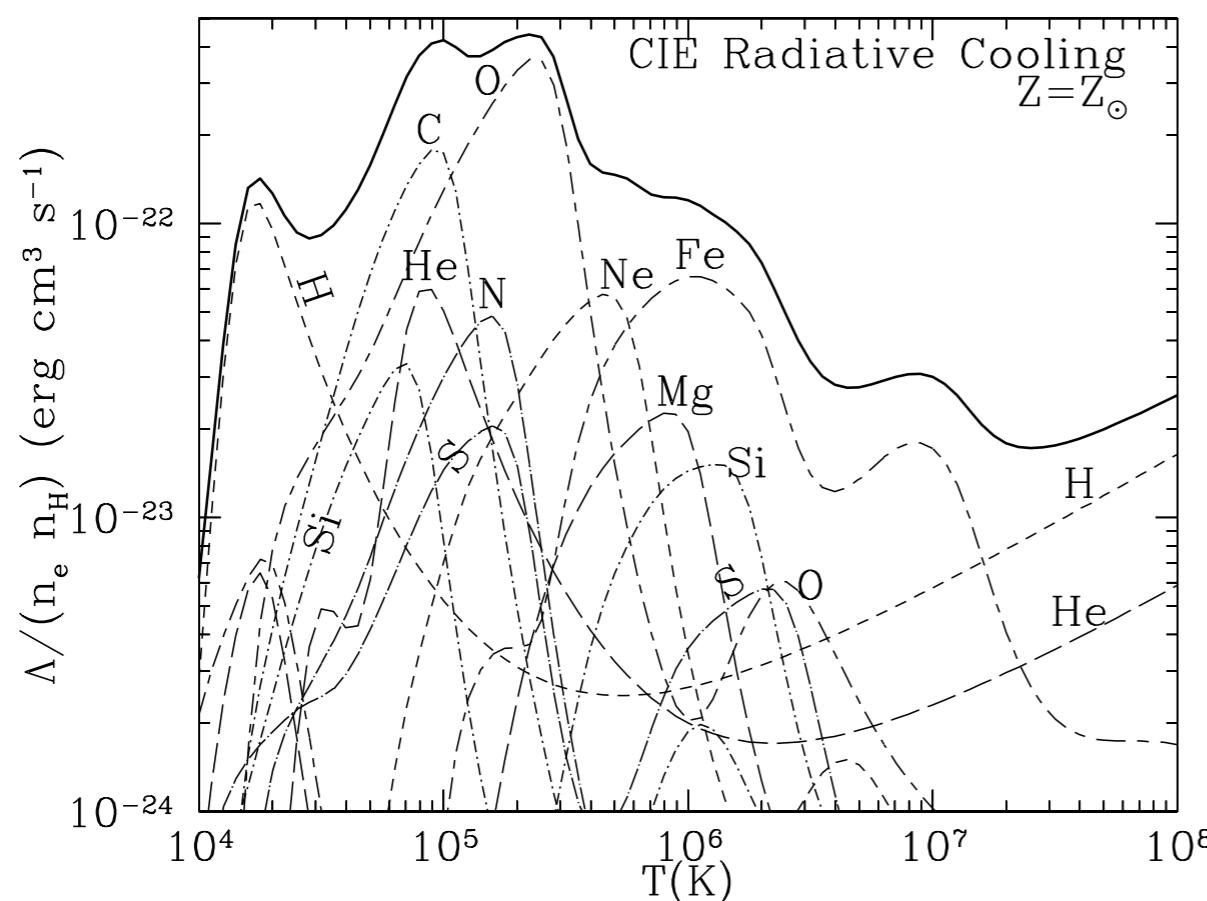

Cooling Function for different abundances

- In most applications, the abundances of elements beyond He can be assumed to be scaled up and down together.

The cooling functions were calculated using CHIANTI.

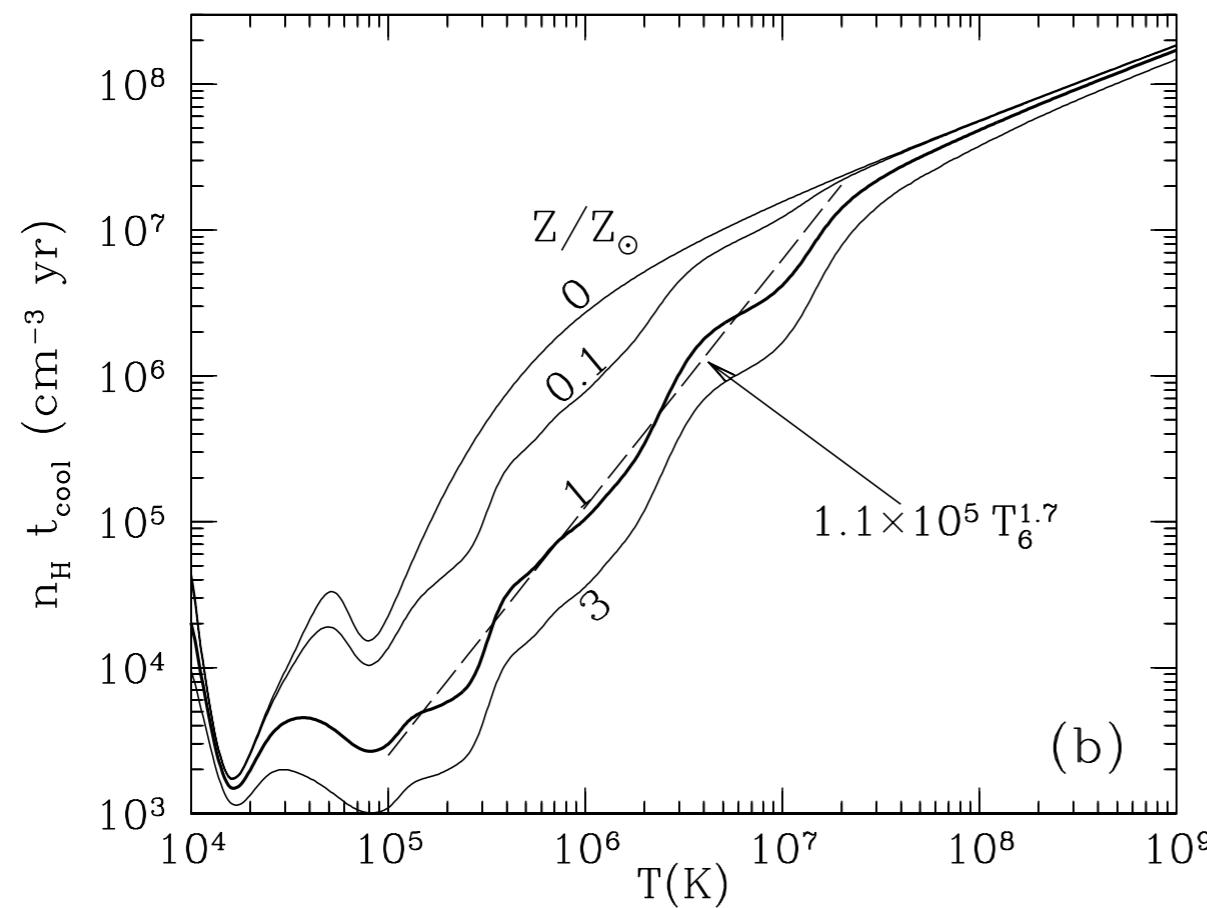

Fig 34.3
Draine

Radiative Cooling Function, with contributions from selected elements

- For $10^{5.8} < T < 10^{7.2}$ K, the cooling is dominated by Mg, Si, and Fe - elements that in cold gas are normally depleted by factors of 5 or more. In this calculation, the solar abundance is assumed.

Fig 34.4
Draine

Cooling time

$$t_{\text{cool}} \approx 1.1 \times 10^5 T_6^{1.7} (n_H/\text{cm}^{-3})^{-1} [\text{yr}]$$

$$(10^5 \lesssim T \lesssim 10^{7.3} \text{ K})$$

for isochoric cooling (constant density)

Cooling Time Scale [isobaric / isochoric]

- Cooling Time scale for two important cases:

- The first law of thermodynamics states that:

Heat added in a system: $dQ = dU + PdV$

- Using a heating and cooling rate per volume Γ and Λ , the change in heat is

$$dQ = (\Gamma - \Lambda)Vdt$$

- The change in the internal energy is

$$dU = (\Gamma - \Lambda)Vdt - PdV$$

- When there is no external heating, the equation for an ideal gas with a degree of freedom f becomes:

$$\begin{aligned} U &= \frac{f}{2}NkT & \longrightarrow & d\left(\frac{f}{2}NkT\right) = -\Lambda Vdt - PdV \\ PV &= NkT \end{aligned}$$

-
- Consider the case of constant pressure or constant volume:

$$PdV = d(PV) - VdP = d(NkT) \quad \text{for } \mathbf{\textit{isobaric cooling (constant pressure)}}$$

$$PdV = 0 \quad \text{for } \mathbf{\textit{isochoric cooling (constant density or volume)}}$$

Therefore,

$$\frac{d}{dt} \left(\frac{f+2}{2} NkT \right) = -\Lambda V \quad \text{for } \mathbf{\textit{isobaric cooling (constant pressure)}}$$

$$\frac{d}{dt} \left(\frac{f}{2} NkT \right) = -\Lambda V \quad \text{for } \mathbf{\textit{isochoric cooling (constant density or volume)}}$$

The cooling time scale are then:

$$t_{\text{cool}} \equiv \frac{T}{|dT/dt|} \Rightarrow t_{\text{cool}} = \frac{f+2}{2} \frac{nkT}{\Lambda} \quad \text{for isobaric cooling}$$

$$n \equiv N/V \quad = \frac{f}{2} \frac{nkT}{\Lambda} \quad \text{for isochoric cooling}$$

Here, the number density includes all particles (molecules, atoms, ions, electrons)

Time Scales in the HIM

- **Cooling time scale:**

- In the HIM with temperatures $T \sim 10^6 - 10^7$ K, the cooling time scale is:

$$t_{\text{cool}} = \frac{5}{2} \frac{n k T}{\Lambda}$$

$$\begin{aligned} n_e &\approx 1.2 n_H \\ n &\approx 2.3 n_H \end{aligned}$$

For fully ionized gas,
one electron from an ionized hydrogen
two electrons from a doubly-ionized helium.

- The cooling time at $T \sim 10^6$ K is

$$t_{\text{cool}} = \frac{5}{2} \frac{2.3}{1.2} \frac{k T}{\Lambda / (n_e n_H)} \frac{1}{n_H}$$

$$\begin{aligned} t_{\text{cool}} &\approx 48 \text{ [Myr]} T_6^{1.7} \left(\frac{n_H}{0.004 \text{ cm}^{-3}} \right)^{-1} \\ &\approx 0.19 \text{ [Myr]} T_6^{1.7} \left(\frac{n_H}{1 \text{ cm}^{-3}} \right)^{-1} \end{aligned}$$

← $\Lambda / n_e n_H \approx 1.1 \times 10^{-22} T_6^{-0.7} \text{ [erg cm}^3 \text{ s}^{-1}\text{]}$

- At $T \sim 10^7$ K, the cooling time is

$$\begin{aligned} t_{\text{cool}} &\approx 7.2 \text{ [Gyr]} T_7^{1/2} \left(\frac{n_H}{0.004 \text{ cm}^{-3}} \right)^{-1} \\ &\approx 29 \text{ [Myr]} T_7^{1/2} \left(\frac{n_H}{1 \text{ cm}^{-3}} \right)^{-1} \end{aligned}$$

← $\Lambda / n_e n_H \approx 2.3 \times 10^{-24} T_6^{0.5} \text{ [erg cm}^3 \text{ s}^{-1}\text{]}$

Given the low density of the HIM, the cooling time of gas is comparable to the age of our galaxy.

-
- ***Recombination and Ionization Time scale:***
 - If collisional ionization could somehow be turned off, the recombination time scale is
$$t_{\text{rec}} = \frac{1}{n_e \alpha_{A,H}} \approx 0.6 \text{ [Gyr]} \left(\frac{n_H}{0.004 \text{ cm}^{-3}} \right)^{-1} \quad [T \approx 10^6 \text{ K}] \quad \alpha_{A,H} \approx 1.5 \times 10^{-14} \text{ [cm}^3 \text{ s}^{-1}\text{]}$$
 - If collisional ionization could suddenly switch on, the collisional ionization time scale is
$$t_{\text{ci}} = \frac{1}{n_e k_{\text{ci}}} \approx 160 \text{ [yr]} \left(\frac{n_H}{0.004 \text{ cm}^{-3}} \right)^{-1} \quad [T \approx 10^6 \text{ K}] \quad k_{\text{ci},H} \approx 5.0 \times 10^{-8} \text{ [cm}^3 \text{ s}^{-1}\text{]}$$
 - These times scales indicates that
 - ▶ If cold neutral hydrogen gas is shock-heated to $\sim 10^6$ K in a time $t_{\text{heat}} \ll t_{\text{ci}}$, it will take a time $t \sim t_{\text{ci}}$ for hydrogen to become ionized. ***During this time interval, the hydrogen will be out of collisional ionization equilibrium (under-ionized than in CIE).***
 - ▶ If highly ionized gas at $\sim 10^6$ K is cooled on a timescale $t_{\text{cool}} \ll t_{\text{rec}}$, and the heating source is turned off, it will take a time $t \sim t_{\text{rec}}$ for the hydrogen to recombine. ***During the intervening time, the gas will be out of CIE (over-ionized than in CIE).*** This is sometimes called “delayed recombination”.

-
- If a gradually cooling gas of the HIM to be remained in CIE, we require $t_{\text{rec}} < t_{\text{cool}}$.

Assuming the recombination rate coefficient at high temperatures

$$\alpha_{A,H} \approx 5 \times 10^{-16} \text{ cm}^3 \text{ s}^{-1} (T/10^7 \text{ K})^{-1.5}$$

- At $T \sim 10^6 \text{ K}$,

$$t_{\text{rec}} = \frac{1}{n_e \alpha_{A,H}} \approx 0.5 \text{ [Gyr]} (T/10^6 \text{ K})^{1.5} (n_{\text{H}}/0.004 \text{ cm}^{-3})^{-1}$$

$$t_{\text{cool}} \approx 48 \text{ [Myr]} T_6^{1.7} (n_{\text{H}}/0.004 \text{ cm}^{-3})^{-1}$$

$$\Rightarrow \frac{t_{\text{rec}}}{t_{\text{cool}}} \approx 10 (T/10^6 \text{ K})^{-0.2}$$

- At $T \sim 10^7 \text{ K}$,

$$t_{\text{rec}} = \frac{1}{n_e \alpha_{A,H}} \approx 16 \text{ [Gyr]} (T/10^7 \text{ K})^{1.5} (n_{\text{H}}/0.004 \text{ cm}^{-3})^{-1}$$

$$t_{\text{cool}} \approx 7.2 \text{ [Gyr]} T_7^{0.5} (n_{\text{H}}/0.004 \text{ cm}^{-3})^{-1}$$

$$\Rightarrow \frac{t_{\text{rec}}}{t_{\text{cool}}} \approx 2.2 (T/10^7 \text{ K})$$

Therefore, ***in the extremely hot regions, the hotter the gas is, the further away it is from CIE.***

Cooling in Shocked Gas

- The hot shocked gas is out of equilibrium, and will start to cool. Thus, the shock will be followed by a radiative zone in which the shock heated gas cools down by radiating away photons.

- At high temperatures $T > 2 \times 10^7 \text{ K}$

- ▶ The cooling is dominated by bremsstrahlung (free-free radiation), for which the specific cooling rate is

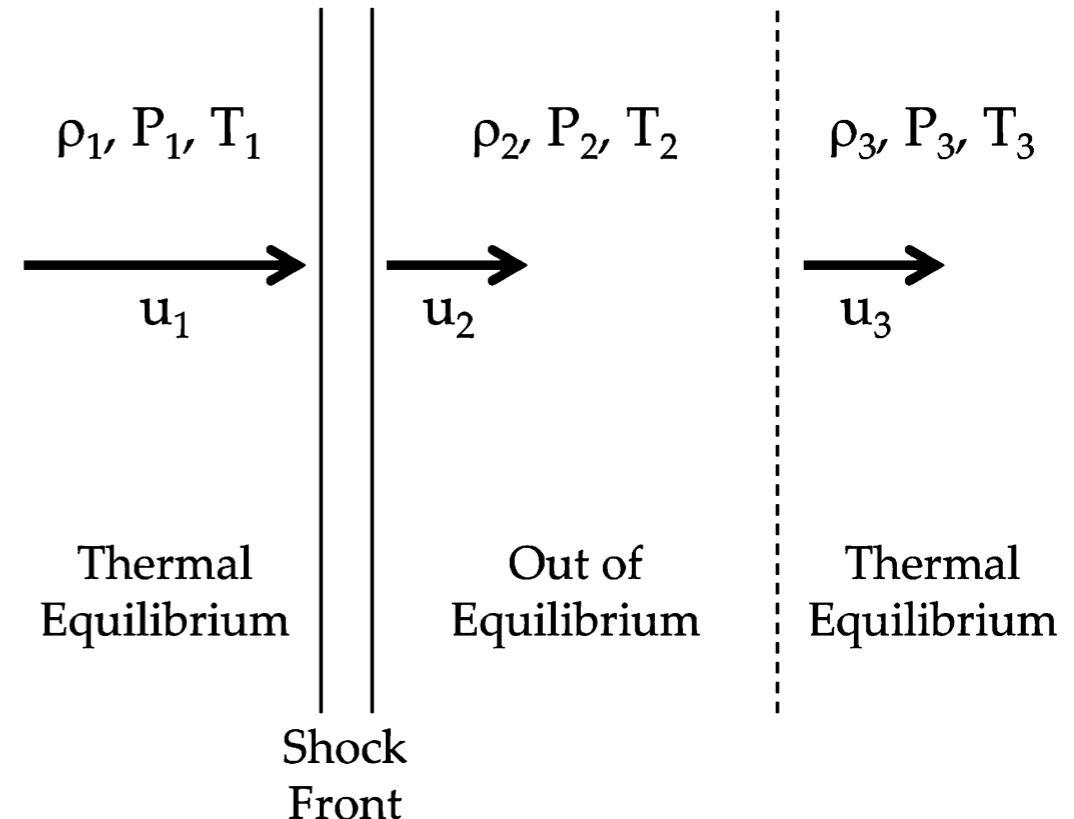

$$\mathcal{L} = 2.7 [\text{erg g}^{-1} \text{s}^{-1}] \left(\frac{T}{10^7 \text{ K}} \right)^{1/2} \left(\frac{n_{\text{H}}}{1 \text{ cm}^{-3}} \right)$$

assuming a gas of fully ionized hydrogen. The specific internal energy of ionized hydrogen is

$$\epsilon = \frac{3kT}{m_{\text{H}}} \approx 2.5 \times 10^{15} [\text{erg g}^{-1}] \left(\frac{T}{10^7 \text{ K}} \right)$$

- ▶ Then, the bremsstrahlung cooling time is

$$\begin{aligned} t_{\text{cool}} &= \frac{\rho \epsilon}{\mathcal{L}} \approx 29 [\text{Myr}] \left(\frac{T}{10^7 \text{ K}} \right)^{1/2} \left(\frac{n_{\text{H}}}{1 \text{ cm}^{-3}} \right)^{-1} \\ &\approx 34 [\text{Myr}] \left(\frac{V_s}{1000 \text{ km s}^{-1}} \right) \left(\frac{n_{\text{H}}}{1 \text{ cm}^{-3}} \right)^{-1} \end{aligned} \quad \begin{array}{c} \curvearrowleft \\ T \simeq \frac{3}{16} \frac{m}{k} V_s^2 \end{array}$$

The structure of a plane parallel radiative shock
[Figure 5.3 Ryden]

-
- ▶ During this time, the gas will move a distance, relative to the shock front:

$$R_{\text{cool}} \approx u_2 t_{\text{cool}} \approx \frac{u_1}{4} t_{\text{cool}}$$

$$\approx 8.7 \text{ [kpc]} \left(\frac{V_s}{1000 \text{ km s}^{-1}} \right)^2 \left(\frac{n_{\text{H}}}{1 \text{ cm}^{-3}} \right)^{-1}$$

This tells us that ***the approximate thickness of the radiative zone for a strong shock is a long distance compared to the scale height of the ISM in our galaxy.*** Thus, the hot gas produced by high-speed shocks doesn't have time to cool before the shock runs out of gas to shock.

- At lower temperature ($10^5 \text{ K} < T < 2 \times 10^7 \text{ K}$), corresponding to slower shock speed ($80 \text{ km s}^{-1} < u_1 = V_s < 1200 \text{ km s}^{-1}$)
- ▶ The collisionally excited lines do most of the cooling, a useful approximation gives

$$t_{\text{cool}} \approx 6600 \text{ [yr]} \left(\frac{V_s}{100 \text{ km s}^{-1}} \right)^{3.4} \left(\frac{n_{\text{H}}}{1 \text{ cm}^{-3}} \right)^{-1}$$

- ▶ This yields a thickness for the radiative zone.

$$R_{\text{cool}} \approx \frac{V_s}{4} t_{\text{cool}} = 0.17 \text{ [pc]} \left(\frac{V_s}{100 \text{ km s}^{-1}} \right)^{4.4} \left(\frac{n_{\text{H}}}{1 \text{ cm}^{-3}} \right)^{-1}$$

- ▶ The shorter time scales and length scales mean that radiative cooling is more effective at changing the structure of slower shocks.

Homework

[Q14]

The “cooling time” $\tau_{\text{cool}} \equiv |d \ln T / dt|^{-1}$. Suppose the power radiated per unit volume Λ can be approximated by

$$\Lambda \approx A n_{\text{H}} n_e \left[T_6^{-0.7} + 0.021 T_6^{1/2} \right]$$

for gas of cosmic abundances, where $A = 1.1 \times 10^{-22} \text{ erg cm}^3 \text{ s}^{-1}$, and $T_6 \equiv T / 10^6 \text{ K}$. Assume the gas to have $n_{\text{He}} = 0.1 n_{\text{H}}$, with both H and He fully ionized.

Compute the cooling time (at constant pressure) due to radiative cooling

- (a) in a supernova remnant at $T = 10^7 \text{ K}$, $n_{\text{H}} = 10^{-2} \text{ cm}^{-3}$.
- (b) for intergalactic gas within a dense galaxy cluster (the “intracluster medium”) with $T = 10^8 \text{ K}$, $n_{\text{H}} = 10^{-3} \text{ cm}^{-3}$.

[Q15]

Consider a strong shock wave propagating into a medium that was initially at rest. Assume the gas to be monatomic ($\gamma = 5/3$). Consider the material just behind the shock front. The gas has an energy density u_{thermal} from random thermal motions, and an energy density u_{flow} from the bulk motion of the shocked gas. If cooling is negligible, calculate the ratio $u_{\text{flow}}/u_{\text{thermal}}$ in the frame of reference where the shock front is stationary.
